#### **Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

# 1. Introduction

# 1.1. Introducing Intel® MPI Benchmarks

Intel® MPI Benchmarks performs a set of MPI performance measurements for point-to-point and global communication operations for a range of message sizes. Intel® MPI Benchmarks is developed using ANSI C plus standard MPI. It is distributed as an open source project to enable use of benchmarks across various cluster architectures and MPI implementations.

The generated benchmark data fully characterizes:

- Performance of a cluster system, including node performance, network latency, and throughput
- Efficiency of the MPI implementation used

The Intel® MPI Benchmarks package consists of the following components:

- IMB-MPI1 benchmarks for MPI-1 functions.
- Two components for MPI-2 functionality:
  - IMB-EXT one-sided communications benchmarks.
  - IMB-IO input/output (I/O) benchmarks.
- Two components for MPI-3 functionality:
  - IMB-NBC benchmarks for non-blocking collective (NBC) operations.
  - IMB-RMA one-sided communications benchmarks. These benchmarks measure the Remote Memory Access (RMA) functionality introduced in the MPI-3 standard.

Each component constitutes a separate executable file. You can run all of the supported benchmarks, or specify a single executable file in the command line to get results for a specific subset of benchmarks.

If you do not have the MPI-2 or MPI-3 extensions available, you can install and use IMB-MPI1 that uses only standard MPI-1 functions.

## 1.2. What's New

This section provides changes for the Intel® MPI Benchmarks as compared to the previous versions of this product.

# 1.2.1. Changes in Intel® MPI Benchmarks 2017 Update 1

This release includes the following updates as compared to the Intel® MPI Benchmarks 2017:

- Added a new option -imb\_barrier. See Command-Line Control.
- The PingPong and PingPing benchmarks are now equivalent to PingPongSpecificSource and PingPingSpecificSource, respectively. Their old behavior (with MPI\_ANY\_SOURCE) is available in PingPongAnySource and PingPingAnySource.

# 1.2.2. Changes in Intel® MPI Benchmarks 2017

This release includes the following updates as compared to the Intel® MPI Benchmarks 4.1 Update 1:

- Changed default values for the -sync and -root shift options. See Command-Line Control.
- Support for the Microsoft\* Visual Studio\* 2015. Microsoft\* Visual Studio\* 2010 support is removed.

• Minor improvements and bug fixes.

## 1.2.3. Changes in Intel® MPI Benchmarks 4.1 Update 1

This release includes the following updates as compared to the Intel® MPI Benchmarks 4.1:

• Minor improvements and bug fixes.

# 1.2.4. Changes in Intel® MPI Benchmarks 4.1

This release includes the following updates as compared to the Intel® MPI Benchmarks 4.0:

- Introduced new benchmarks: Uniband and Biband. See Parallel Transfer Benchmarks.
- Introduced new options: -sync and -root shift. See Command-Line Control.

# 1.2.5. Changes in Intel® MPI Benchmarks 4.0

This release includes the following updates as compared to the Intel® MPI Benchmarks 3.2.4:

- Introduced new components IMB-NBC and IMB-RMA that conform to the MPI-3.0 standard.
- Introduced a new feature to set the appropriate policy for automatic calculation of iterations. You can set the policy using the -iter and -iter policy options.
- Added new targets to the Linux\* OS Makefiles:
  - NBC for building IMB-NBC
  - RMA for building IMB-RMA
- Updated Microsoft\* Visual Studio\* solutions to include the IMB-NBC and IMB-RMA targets.
- Support for the Microsoft\* Visual Studio\* 2013. Microsoft\* Visual Studio\* 2008 support is removed.

#### **Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## 1.3. About this Document

This User's Guide provides a complete description of the Intel® MPI Benchmarks, including usage information and detailed description of each benchmark.

The following conventions are used in this document:

Style	Description	
This type style	Commands, arguments, options, file names	

THIS_TYPE_STYLE	Environment variables
<this style="" type=""> Placeholders for actual values</this>	
[ items ]	Optional items
{ item   item }	Selectable items separated by vertical bar(s)

# 1.4. Getting Help and Support

Your feedback is very important to us. To receive technical support for the tools provided in this product and technical information including FAQ's and product updates, you need to register for an Intel® Premier Support account at the Registration Center.

This package is supported by Intel® Premier Support. Direct customer support requests at: https://premier.intel.com

General information on Intel® product-support offerings may be obtained at: http://www.intel.com/software/products/support

Intel® MPI Benchmarks home page can be found at: http://www.intel.com/go/imb

When submitting a support issue to Intel® Premier Support, please provide specific details of your problem, including:

- The Intel® MPI Benchmarks package name and version information.
- Host architecture (for example, Intel® 64 architecture).
- Compiler(s) and versions.
- Operating system(s) and versions.
- Specifics on how to reproduce the problem. Include makefiles, command lines, small test cases, and build instructions.

## 1.5. Related Information

For more information, you can see the following related resources:

- Intel® MPI Benchmarks Download Page
- Intel® MPI Library Product

# 2. Installation and Quick Start

This section explains how to install and start using the Intel® MPI Benchmarks.

# 2.1. Memory and Disk Space Requirements

The table below lists memory requirements for benchmarks run with the default settings (standard mode) and with the user-defined settings (optional mode). In this table:

- Q is the number of active processes.
- X is the maximal size of the passing message.

Benchmarks	Standard Mode	Optional Mode	
Alltoall	Q*8 MB	Q*2X bytes	
Allgather, Allgatherv	(Q+1)*4 MB	(Q+1)*X bytes	
Exchange	12 MB	3X bytes	
All other MPI-1 benchmarks	8 MB	2X bytes	
IMB-EXT	IB-EXT 80 MB 2 max (X, OVERALL_VOL		
IMB-IO 32 MB 3X bytes		3X bytes	
Ialltoall, Ialltoall_pure Q*8 MB		Q*2X bytes	
Iallgather, Iallgatherv, Iallgather_pure, Iallgatherv_pure	(Q+1)*4 MB	(Q+1)*X bytes	
All other IMB-NBC benchmarks	8 MB	2X bytes	
Compare_and_swap	12 B	12 B	
Exchange_put, Exchange_get	16 MB	4X bytes	
All other IMB-RMA benchmarks	8 MB	2X bytes	

#### NOTE

If you do not select the -cache flag, add 2X cache size to all of the above.

For IMB-IO benchmarks, make sure you have enough disk space available:

- 16MB in the standard mode
- max (X, OVERALL VOL) bytes in the optional mode

For instructions on enabling the optional mode, see Parameters Controlling Intel® MPI Benchmarks.

# 2.2. Software Requirements

To run the Intel® MPI Benchmarks, you need:

- cpp, ANSI C compiler, gmake on Linux\* OS or Unix\* OS.
- Enclosed Microsoft Visual\* C++ solutions as the basis for Microsoft Windows\* OS.
- MPI installation, including a startup mechanism for parallel MPI programs.

# 2.3. Installing Intel® MPI Benchmarks

To install the Intel® MPI Benchmarks, unpack the installation file.

If you install the product within Intel® Parallel Studio XE Cluster Edition, the default installation directory will be: <psxe install dir>/imb

The installation directory structure is as follows:

- ReadMe IMB.txt
- ./doc documentation directory that contains the User Guide, in PDF and HTML formats:
  - IMB\_Users\_Guide.pdf
  - IMB Users Guide.htm
- ./license license agreement directory that contains the following files:
  - license.txt specifies the source code license granted to you.
  - use-of-trademark-license.txt-specifies the license for using the name and/or trademark of the Intel® MPI Benchmarks.
- ./src program source- and Makefiles.
- ./WINDOWS Microsoft\* Visual Studio\* solution files.

For basic instructions on how to use the Intel® MPI Benchmarks, see ReadMe IMB.txt.

#### See Also

Building Intel® MPI Benchmarks

# 2.4. Building Intel® MPI Benchmarks

### 2.4.1. Linux\* OS

To build the benchmarks for Linux\* OS, do the following:

- 1. Set the CC variable to point to the appropriate compiler wrapper, mpicc or mpicc.
- 2. Run one or more makefile commands listed below.

Command	Description
make clean	Remove legacy binary object files and executable files
make MPI1 Build the executable file for the IMB-MPI1 component.	
make EXT	Build the executable file for one-sided communications benchmarks.

make IO	Build the executable file for I/O benchmarks.
make NBC	Build the executable file for IMB-NBC benchmarks.
make RMA	Build the executable file for IMB-RMA benchmarks.
make all	Build all executable files available.

To build the benchmarks for Intel® Many Integrated Core Architecture (Intel® MIC Architecture), follow these steps:

1. Build the Intel MPI Benchmarks for the host system:

```
host$ source <psxe_install_dir>/bin/psxevars.sh
host$ cd <path to IMB directory>/src
host$ make -f make_ict
```

2. Build the Intel MPI Benchmarks for the target system based on the Intel® MIC Architecture.

```
host$ cd <path to IMB directory>/src
host$ make -f make ict mic
```

For details on running the resulting executable files on the Intel® MIC Architecture, see the *Intel® MPI Library* documentation.

### 2.4.2. Windows\* OS

To build the benchmarks for IMB-MPI1, IMB-IO, IMB-EXT, IMB-NBC, or IMB-RMA, follow these steps:

1. Check the environment variable settings for Include, Lib, and Path. Make sure they are set in accordance with this table:

Intel® 64 Architecture Settings	IA-32 Architecture Settings	
%I_MPI_ROOT%\intel64\include	%I_MPI_ROOT%\ia32\include	
%I_MPI_ROOT%\intel64\lib	%I_MPI_ROOT%\ia32\lib	
%I_MPI_ROOT%\intel64\bin	%I_MPI_ROOT%\ia32\bin	

#### **NOTE**

- 2. Intel® MPI Library 5.0 does not support the IA-32 architecture. Use an earlier version of Intel MPI Library to build IA-32 architecture benchmarks.
- 3. Go to the subfolder that corresponds to the Intel® MPI Benchmarks component you would like to build and the Microsoft\* Visual Studio\* version installed on your system. For example, to build IMB-EXT\_exe with the Visual\* Studio\* 2010, go to IMB-EXT\_VS\_2010.
- 4. Open the .vcproj or .vcxproj file in Visual Studio\*. The executable file for one of the Intel MPI Benchmarks components is created:
  - IMB-EXT.exe
  - IMB-IO.exe
  - IMB-MPI1.exe
  - IMB-NBC.exe
  - IMB-RMA.exe

- 5. From the **Solution Platforms** drop-down list, choose the required architecture (**x64** or **Win32**).
- 6. From the **Solution Configurations** drop-down list, choose **Release**.
- 7. Highlight the project folder in the **Solution Explorer**.
- 8. Go to **Project > Properties** to open **Configuration Properties** dialog box. Make sure you have something like the following settings:

6.

Setting	Value	Notes		
General > Project Defaults				
Character Set	Use Multi-Byte Character Set			
	Debugging			
Debugger to launch	Local Windows Debugger	Depending on your system configuration, you may select other debuggers.		
Command	<ul><li>x64: %I_MPI_ROOT%\intel64\bin\mpiexec.exe</li><li>IA-32: %I_MPI_ROOT%\ia32\bin\mpiexec.exe</li></ul>			
Command Arguments	-n 2 %TargetPath%	%TargetPath% should be quoted as in: "-n 2 %TargetPath%"		
	C/C++ > General			
Additional Include Directories	<ul><li>x64: %I_MPI_ROOT%\intel64\include</li><li>IA-32: %I_MPI_ROOT%\ia32\include</li></ul>			
Warning Level	to Level 1 (/W1)			
C/C++ > Preprocessor				
Preprocessor Definition	<ul> <li>IMB-EXT: WIN_IMB, _CRT_SECURE_NO_DEPRECATE, EXT</li> <li>IMB-IO: WIN_IMB, _CRT_SECURE_NO_DEPRECATE, MPIIO</li> <li>IMB-MPI1: WIN_IMB, _CRT_SECURE_NO_DEPRECATE, MPII</li> <li>IMB-NBC: WIN_IMB, _CRT_SECURE_NO_DEPRECATE, NBC</li> <li>IMB-RMA: WIN_IMB, _CRT_SECURE_NO_DEPRECATE, RMA</li> </ul>			
	Linker > Input			

Additional	•	x64:%I_MPI_ROOT%\intel64\lib\impi.lib	
Dependencies	•	IA-32:%I_MPI_ROOT%\ia32\lib\impi.lib	

- 7.
- 8. Go to **Build > Build Solution** to create an executable file.
- 9. Run the executable file using **Debug > Start Without Debugging** command.

#### See Also

Running Intel® MPI Benchmarks

# 2.5. Running Intel® MPI Benchmarks

To run the Intel® MPI Benchmarks, use the following command-line syntax:

mpirun -np <P> IMB-<component> [arguments]

#### where

- <P> is the number of processes. P=1 is recommended for all I/O and message passing benchmarks except the single transfer ones.
- <component> is the component-specific suffix that can take MPI1, EXT, IO, NBC, and RMA values.

By default, all benchmarks run on Q active processes defined as follows:

```
Q=[1,] 2, 4, 8, ..., largest 2^{x}
```

For example, if P=11, the benchmarks run on Q=[1,]2,4,8,11 active processes. Single transfer IMB-IO benchmarks run with Q=1. Single transfer IMB-EXT and IMB-RMA benchmarks run with Q=2.

To pass control arguments other than P, you can use (argc, argv). Process 0 in MPI\_COMM\_WORLD reads all command-line arguments and broadcasts them to all other processes. Control arguments can define various features, such as time measurement, message length, and selection of communicators. For details, see Command-Line Control.

#### See Also

Command-Line Control
Parameters Controlling Intel® MPI Benchmarks

# 2.6. Running Benchmarks in Multiple Mode

Intel® MPI Benchmarks provides a set of elementary MPI benchmarks.

You can run all benchmarks in the following modes:

- Standard (default) the benchmarks run in a single process group.
- Multiple the benchmarks run in several process groups.

To run the benchmarks in the multiple mode, add the multi- prefix to the benchmark name.

In the multiple mode, the number of groups may differ depending on the benchmark. For example, if PingPong is running on N≥4 processes, N/2 separate groups of two processes are formed. These process groups are running PingPong simultaneously. Thus, the benchmarks of the single transfer class behave as parallel transfer benchmarks when run in the multiple mode.

### **See Also**

Classification of MPI-1 Benchmarks Classification of MPI-2 Benchmarks MPI-3 Benchmarks

# 3. MPI-1 Benchmarks

IMB-MPI1 component of the Intel® MPI Benchmarks provides benchmarks for MPI-1 functions. IMB-MPI1 contains the following benchmarks:

Standard Mode	Multiple Mode
PingPong	Multi-PingPong
PingPongSpecificSource (excluded by default)	Multi-PingPongSpecificSource (excluded by default)
PingPongAnySource (excluded by default)	Multi-PingPongAnySource (excluded by default)
PingPing	Multi-PingPing
PingPingSpecificSource (excluded by default)	Multi-PingPingSpecificSource (excluded by default)
PingPingAnySource (excluded by default)	Multi-PingPingAnySource (excluded by default)
Sendrecv	Multi-Sendrecv
Exchange	Multi-Exchange
Uniband	Multi-Uniband
Biband	Multi-Biband
Bcast	Multi-Bcast
Allgather	Multi-Allgather
Allgatherv	Multi-Allgatherv
Scatter	Multi-Scatter
Scatterv	Multi-Scatterv
Gather	Multi-Gather
Gatherv	Multi-Gatherv
Alltoall	Multi-Alltoall
Alltoallv	Multi-Alltoallv
Reduce	Multi-Reduce

Reduce_scatter	Multi-Reduce_scatter
Allreduce	Multi-Allreduce
Barrier	Multi-Barrier

# 3.1. Classification of MPI-1 Benchmarks

Intel® MPI Benchmarks introduces the following classes of benchmarks:

- Single Transfer
- Parallel Transfer
- Collective benchmarks

The following table lists the MPI-1 benchmarks in each class:

Single Transfer	Parallel Transfer	Collective
PingPong	Sendrecv	Bcast Multi-Bcast
PingPongSpecificSource	Exchange	Allgather Multi-Allgather
PingPongAnySource	Multi-PingPong	Allgatherv Multi-Allgatherv
PingPing	Multi-PingPing	Alltoall Multi-Alltoall
PingPingSpecificSource	Multi-Sendrecv	Alltoallv Multi-Alltoallv
PingPingAnySource	Multi-Exchange	Scatter Multi-Scatter
	Uniband	Scatterv Multi-Scatterv
	Biband	Gather Multi-Gather
	Multi-Uniband	Gatherv Multi-Gatherv
	Multi-Biband	Reduce Multi-Reduce
		Reduce_scatter

	Multi-Reduce_scatter
	Allreduce Multi-Allreduce
	Barrier Multi-Barrier

Each class interprets results in a different way.

## 3.1.1. Single Transfer Benchmarks

Single transfer benchmarks involve two active processes into communication. Other processes wait for the communication completion. Each benchmark is run with varying message lengths. The timing is averaged between two processes. The basic MPI data type for all messages is MPI BYTE.

Throughput values are measured in MBps and can be calculated as follows:

throughput = X/time

#### where

- time is measured in  $\mu$  sec.
- X is the length of a message, in bytes.

### 3.1.2. Parallel Transfer Benchmarks

Parallel transfer benchmarks involve more than two active processes into communication. Each benchmark runs with varying message lengths. The timing is averaged over multiple samples. The basic MPI data type for all messages is  $MPI_BYTE$ . The throughput calculations of the benchmarks take into account the multiplicity nmsg of messages outgoing from or incoming to a particular process. For the Sendrecv benchmark, a particular process sends and receives X bytes, the turnover is 2X bytes, nmsg=2. For the Exchange benchmark, the turnover is 4X bytes, nmsg=4.

Throughput values are measured in MBps and can be calculated as follows:

throughput = nmsg\*X/time,

### where

- time is measured in μsec.
- X is the length of a message, in bytes.

## 3.1.3. Collective Benchmarks

Collective benchmarks measure MPI collective operations. Each benchmark is run with varying message lengths. The timing is averaged over multiple samples. The basic MPI data type for all messages is MPI\_BYTE for pure data movement functions and MPI FLOAT for reductions.

Collective benchmarks show bare timings.

# 3.2. Single Transfer Benchmarks

The following benchmarks belong to the single transfer class:

- PingPong
- PingPongSpecificSource

- PingPongAnySource
- PingPing
- PingPingSpecificSource
- PingPingAnySource

See sections below for definitions of these benchmarks.

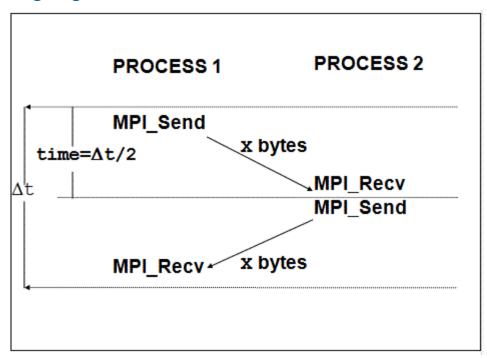

# 3.2.1. PingPong, PingPongSpecificSource, PingPongAnySource

Use PingPong, PingPongSpecificSource, and PingPongAnySource for measuring startup and throughput of a single message sent between two processes. PingPongAnySource uses the MPI\_ANY\_SOURCE value for destination rank, while PingPong and PingPongSpecificSource use an explicit value.

### **PingPong Definition**

Property	Description
Measured pattern	As symbolized between $\bullet$ in the figure below. This benchmark runs on two active processes (Q=2) .
MPI routines	MPI_Send, MPI_Recv
MPI data type	MPI_BYTE
Reported timings	time= $\Delta t/2$ (in $\mu sec$ ) as indicated in the figure below.
Reported throughput	X/time

### **PingPong Pattern**

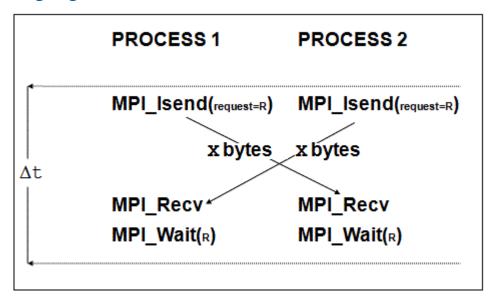

# 3.2.2. PingPing, PingPingSpecificSource, PingPingAnySource

PingPing, PingPingSpecificSource, and PingPingAnySource measure startup and throughput of single messages that are obstructed by oncoming messages. To achieve this, two processes communicate with each other using MPI\_Isend/MPI\_Recv/MPI\_Wait calls. The MPI\_Isend calls are issued simultaneously by both processes. For destination rank, PingPingAnySource uses the MPI\_ANY\_SOURCE value, while PingPing and PingPingSpecificSource use an explicit value.

### **PingPing Definition**

Property	Description
Measured pattern	As symbolized between in the figure below. This benchmark runs on two active processes ( $Q=2$ ).
MPI routines	MPI_Isend/MPI_Wait, MPI_Recv
MPI data type	MPI_BYTE
Reported timings	time=Δt(in μsec)
Reported throughput	X/time

### **PingPing Pattern**

# 3.3. Parallel Transfer Benchmarks

The following benchmarks belong to the parallel transfer class:

- Sendrecv
- Exchange
- Uniband
- Biband
- Multi-PingPong
- Multi-PingPing
- Multi-Sendrecv
- Multi-Exchange
- Multi-Uniband
- Multi-Biband

See sections below for definitions of these benchmarks.

#### **NOTE**

The definitions of the multiple mode benchmarks are analogous to their standard mode counterparts in the single transfer class.

### 3.3.1. Sendrecv

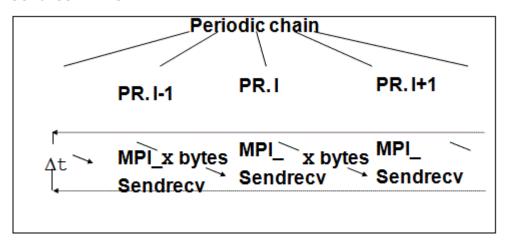

The Sendrecv benchmark is based on MPI\_Sendrecv. In this benchmark, the processes form a periodic communication chain. Each process sends a message to the right neighbor and receives a message from the left neighbor in the chain. The turnover count is two messages per sample (one in, one out) for each process.

In the case of two processes, Sendrecv is equivalent to the PingPing benchmark of IMB1.x. For two processes, it reports the bidirectional bandwidth of the system, as obtained by the optimized  $MPI\_Sendrecv$  function.

#### **Sendrecy Definition**

Property	Description
Measured pattern	As symbolized between •••••••••••••••••••••••••••••••••••
MPI routines	MPI_Sendrecv
MPI data type	MPI_BYTE
Reported timings	time=At (in µsec) as indicated in the figure below.
Reported throughput	2X/time

#### **Sendrecy Pattern**

# 3.3.2. Exchange

Exchange is a communication pattern that often occurs in grid splitting algorithms (boundary exchanges). The group of processes is similar to a periodic chain, and each process exchanges data with both left and right neighbor in the chain.

The turnover count is four messages per sample (two in, two out) for each process.

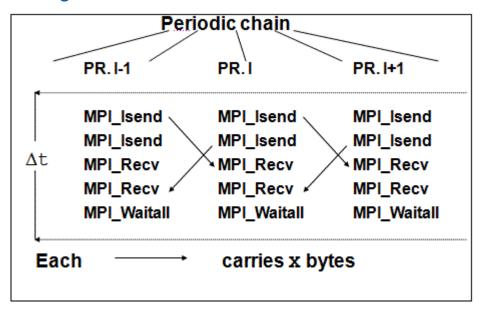

For two Isend messages, separate buffers are used.

### **Exchange Definition**

Property	Description
Measured pattern	As symbolized between in the figure below.
MPI routines	MPI_Isend/MPI_Waitall, MPI_Recv
MPI data type	MPI_BYTE

Reported timings	time=Δt (in μsec)
Reported throughput	4X/time

#### **Exchange Pattern**

### **3.3.3. Uniband**

The Uniband benchmark measures the cumulative bandwidth and message rate values. To achieve this, the first half of ranks communicates with the second half using MPI\_Isend/MPI\_Recv/MPI\_Wait calls. In case of the odd number of processes, one of them does not participate in the message exchange. The bunch of MPI\_Isend calls are issued by each rank in the first half of ranks to its counterpart from the second half of ranks. The number of messages issued at each iteration step is defined with the MAX\_WIN\_SIZE constant. The same buffer is used for every send event in the iteration.

#### **Uniband Definition**

Property	Description
Measured pattern	(MAX_WIN_SIZE *MPI_Isend)/(MAX_WIN_SIZE *MPI_Irecv)/Waitall
MPI data type	MPI_BYTE (origin and target)
Reported message rate	MAX_WIN_SIZE*N/MAX(process_timings), where N is the number of communicating pairs
Reported throughput	MBps (msg_rate *size_in_bytes/ 1000000.0)

## 3.3.4. Biband

The Biband measures the cumulative bandwidth and message rate values. To achieve this, the first half of ranks communicates with the second half using MPI Isend/MPI Recv/MPI Wait calls. In case of the odd

number of processes, one of them does not participate in the message exchange. The bunch of MPI\_Isend calls are issued by each rank in the first half of ranks to its counterpart from the second half of ranks, and vice versa. The number of messages issued at each iteration step is defined with the MAX\_WIN\_SIZE constant. The same buffer is used for every send event in the iteration.

#### **Uniband Definition**

Property	Description
Measured pattern	(MAX_WIN_SIZE *MPI_Isend)/(MAX_WIN_SIZE *MPI_Irecv)/Waitall
MPI data type	MPI_BYTE (origin and target)
Reported message rate	2*MAX_WIN_SIZE*N/MAX(process_timings), where N is the number of communicating pairs
Reported throughput	MBps (msg_rate *size_in_bytes/ 1000000.0)

# 3.4. Collective Benchmarks

The following benchmarks belong to the collective class:

- Bcast/multi-Bcast
- Allgather/multi-Allgather
- Allgatherv/multi-Allgatherv
- Alltoall/multi-Alltoall
- Alltoallv/multi-Alltoallv
- Scatter/multi-Scatter
- Scatterv/multi-Scatterv
- Gather/multi-Gather
- Gatherv/multi-Gatherv
- Reduce/multi-Reduce
- Reduce scatter/multi-Reduce scatter
- Allreduce/multi-Allreduce
- Barrier/multi-Barrier

See sections below for definitions of these benchmarks.

## 3.4.1. Reduce

The benchmark for the MPI\_Reduce function. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. The root of the operation is changed round-robin.

Property	Description	
Measured pattern	MPI_Reduce	

MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

## 3.4.2. Reduce\_scatter

The benchmark for the MPI\_Reduce\_scatter function. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. In the scatter phase, the L items are split as evenly as possible. To be exact, for np number of processes:

L = r\*np+s

#### where

- r = [L/np]
- $s = L \mod np$

In this case, the process with rank i gets:

- r+1 items when i<s
- r items when i≥s

Property	Description
Measured pattern	MPI_Reduce_scatter
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	None

## 3.4.3. Allreduce

The benchmark for the MPI\_Allreduce function. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI FLOAT. The MPI operation is MPI SUM.

Property	Description
Measured pattern	MPI_Allreduce
MPI data type	MPI_FLOAT

MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	None

# 3.4.4. Allgather

The benchmark for the MPI\_Allgather function. Every process inputs X bytes and receives the gathered X\*np bytes, where np is the number of processes.

Property	Description
Measured pattern	MPI_Allgather
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

# 3.4.5. Allgatherv

The benchmark for the MPI\_Allgatherv function. Every process inputs X bytes and receives the gathered X\*np bytes, where np is the number of processes. Unlike Allgather, this benchmark shows whether MPI produces overhead.

Property	Description
Measured pattern	MPI_Allgatherv
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

# **3.4.6. Scatter**

The benchmark for the MPI\_Scatter function. The root process inputs X\*np bytes (X for each process). All processes receive X bytes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Scatter
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i

Reported timings	Bare time
Reported throughput	None

## **3.4.7. Scattery**

The benchmark for the  $\mathtt{MPI\_Scatterv}$  function. The root process inputs  $\mathtt{X*np}$  bytes ( $\mathtt{X}$  for each process). All processes receive  $\mathtt{X}$  bytes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Scatterv
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

### 3.4.8. Gather

The benchmark for the  $MPI\_Gather$  function. The root process inputs X\*np bytes (X from each process). All processes receive X bytes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Gather
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

## **3.4.9. Gathery**

The benchmark for the MPI\_Gatherv function. All processes input X bytes. The root process receives X\*np bytes, where np is the number of processes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Gatherv
MPI data type	MPI_BYTE

Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

## 3.4.10. Alltoall

The benchmark for the MPI\_Alltoall function. In the case of np number of processes, every process inputs X\*np bytes (X for each process) and receives X\*np bytes (X from each process).

Property	Description
Measured pattern	MPI_Alltoall
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

### 3.4.11. Bcast

The benchmark for  $\mathtt{MPI\_Bcast}$ . The root process broadcasts  $\mathtt{X}$  bytes to all other processes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Bcast
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

## 3.4.12. Barrier

The benchmark for the MPI Barrier function.

Property	Description
Measured pattern	MPI_Barrier
Reported timings	Bare time
Reported throughput	None

# 4. MPI-2 Benchmarks

Intel® MPI Benchmarks provides benchmarks for MPI-2 functions in two components: IMB-EXT and IMB-IO. The table below lists all MPI-2 benchmarks available and specifies whether they support the aggregate mode. For I/O benchmarks, the table also lists nonblocking flavors.

Benchmark	Aggregate Mode	Non-blocking Mode
	IMB-EXT	
Window Multi-Window		
Unidir_Put Multi-Unidir_Put	Supported	
Unidir_Get Multi-Unidir_Get	Supported	
Bidir_Get Multi-Bidir_Get	Supported	
Bidir_Put Multi-Bidir_Put	Supported	
Accumulate Multi-Accumulate	Supported	
Benchmark	Aggregate Mode	Non-blocking Mode
	IMB-IO	
Open_Close Multi-Open_Close		
S_Write_indv Multi-S_Write_indv	Supported	S_IWrite_indv Multi-S_IWrite_indv
S_Read_indv Multi-S_Read_indv		S_IRead_indv Multi-S_IRead_indv
S_Write_expl Multi-S_Write_expl	Supported	S_IWrite_expl Multi-IS_Write_expl
S_Read_expl Multi-S_Read_expl		S_IRead_expl Multi-IS_Read_expl
P_Write_indv	Supported	P_IWrite_indv

Multi-P_Write_indv		Multi-P_IWrite_indv
P_Read_indv		P_IRead_indv
Multi-P_Read_indv		Multi-P_IRead_indv
P Write expl	Supported	P IWrite expl
Multi-P_Write_expl		Multi-P_IWrite_expl
P Read expl		P_IRead_expl
Multi-P_Read_expl		Multi-P_IRead_expl
P Write shared	Supported	P IWrite shared
Multi-P_Write_shared		Multi-P_IWrite_shared
P_Read_shared		P IRead shared
Multi-P_Read_shared		Multi-P_IRead_shared
P Write priv	Supported	P IWrite priv
Multi-P_Write_priv		Multi-P_IWrite_priv
P Read priv		P IRead priv
Multi-P_Read_priv		Multi-P_IRead_priv
C Write indv	Supported	C IWrite indv
Multi-C_Write_indv		Multi-C_IWrite_indv
C Read indv		C IRead indv
Multi-C_Read_indv		Multi-C_IRead_indv
C Write expl	Supported	C IWrite expl
Multi-C_Write_expl		Multi-C_IWrite_expl
C_Read_expl		C_IRead_expl
Multi-C_Read_expl		Multi-C_IRead_expl
C_Write_shared	Supported	C_IWrite_shared
Multi-C_Write_shared		Multi-C_IWrite_shared
C Read shared		C IRead shared
Multi-C_Read_shared		Multi-C_IRead_shared

Benchmark Modes IMB-IO Nonblocking Benchmarks

# **4.1. Naming Conventions**

MPI-2 benchmarks have the following naming conventions:

Convention	Description
Unidir/Bidir	Unidirectional/bidirectional one-sided communications. These are the one-sided equivalents of PingPong and PingPing.
S_	Single transfer benchmark.
c_	Collective benchmark.
P_	Parallel transfer benchmark.
expl	I/O with explicit offset.
indv	I/O with an individual file pointer.
shared	I/O with a shared file pointer.
priv	I/O with an individual file pointer to one private file for each process opened for MPI_COMM_SELF.
[ACTION]	A placeholder for Read or Write component of the benchmark name.
I	Non-blocking flavor. For example, <code>S_IWrite_indv</code> is the nonblocking flavor of the <code>S_IWrite_indv</code> benchmark.
Multi-	The benchmark runs in the multiple mode.

# 4.2. IMB-MPI-2 Benchmark Classification

Intel® MPI Benchmarks introduces three classes of benchmarks:

- Single Transfer
- Parallel Transfer
- Collective

Each class interprets results in a different way.

#### **NOTE**

The following benchmarks do not belong to any class:

• Window - measures overhead of one-sided communications for the MPI\_Win\_create / MPI\_Win\_free functions

 Open\_close - measures overhead of input/output operations for the MPI File open / MPI File close functions

## 4.2.1. Single Transfer Benchmarks

This class contains benchmarks of functions that operate on a single data element transferred between one source and one target. For MPI-2 benchmarks, the source of the data transfer can be an MPI process or, in the case of Read benchmarks, an MPI file. The target can be an MPI process or an MPI file.

For I/O benchmarks, the single transfer is defined as an operation between an MPI process and an individual window or a file.

- Single transfer IMB-EXT benchmarks only run with two active processes.
- Single transfer IMB-IO benchmarks only run with one active process.

### 4.2.2. Parallel Transfer Benchmarks

This class contains benchmarks of functions that operate on several processes in parallel. The benchmark timings are produced under a global load. The number of participating processes is arbitrary.

In the Parallel Transfer, more than one process participates in the overall pattern.

The final time is measured as the maximum of timings for all single processes. The throughput is related to that time and the overall amount of transferred data (sum over all processes).

### 4.2.3. Collective Benchmarks

This class contains benchmarks of functions that are collective as provided by the MPI standard. The final time is measured as the maximum of timings for all single processes. The throughput is not calculated.

## 4.2.4. MPI-2 Benchmarks Classification

Single Transfer	Parallel Transfer	Collective	Other
Unidir_Get	Multi_Unidir_Get	Accumulate	Window
Unidir_Put	Multi_Unidir_Put	Multi_Accumulate	Multi_Window
Bidir_Get	Multi_Bidir_Get		
Bidir_Put	Multi_Bidir_Put		
S_[I]Write_indv	P_[I]Write_indv	C_[I]Write_indv	Multi- C_[I]Write_indv
S_[I]Write_indv	P_[I]Write_indv	C_[I]Write_indv Multi- C_[I]Write_indv	Open_close Multi-Open_close
S_[I]Read_indv	P_[I]Read_indv	C_[I]Read_indv Multi- C_[I]Read_indv	

S_[I]Write_expl	P_[I]Write_expl	C_[I]Write_expl Multi- C_[I]Write_expl
S_[I]Read_expl	P_[I]Read_expl	C_[I]Read_expl Multi- C_[I]Read_expl
	P_[I]Write_shared	C_[I]Write_shared Multi- C_[I]Write_shared
	P_[I]Read_shared	C_[I]Read_shared Multi- C_[I]Write_shared
	P_[I]Write_priv P_[I]Read_priv	

# 4.3. MPI-2 Benchmark Modes

MPI-2 benchmarks can run in the following modes:

- Blocking/nonblocking mode. These modes apply to the IMB-IO benchmarks only. For details, see sections IMB-IO Blocking Benchmarks and IMB-IO Nonblocking Benchmarks.
- Aggregate/non-aggregate mode. Non-aggregate mode is not available for nonblocking flavors of IMB-IO benchmarks.

The following example illustrates aggregation of M transfers for IMB-EXT and blocking Write benchmarks:

```
Select a repetition count M
time = MPI Wtime();
issue M disjoint transfers
assure completion of all transfers
time = (MPI Wtime() - time) / M
```

#### In this example:

- M is a repetition count:
  - M = 1 in the non-aggregate mode
  - M = n\_sample in the aggregate mode. For the exact definition of n\_sample see the Actual Benchmarking section.
- A transfer is issued by the corresponding one-sided communication call (for IMB-EXT) and by an MPI-IO write call (for IMB-IO).
- *Disjoint* means that multiple transfers (if M>1) are to/from disjoint sections of the window or file. This permits to avoid misleading optimizations when using the same locations for multiple transfers.

The variation of M provides important information about the system and the MPI implementation, crucial for application code optimizations. For example, the following possible internal strategies of an implementation could influence the timing outcome of the above pattern.

- Accumulative strategy. Several successive transfers (up to M in the example above) are accumulated
  without an immediate completion. At certain stages, the accumulated transfers are completed as a
  whole. This approach may save time of expensive synchronizations. This strategy is expected to
  produce better results in the aggregate case as compared to the non-aggregate one.
- Non-accumulative strategy. Every Transfer is completed before the return from the corresponding function. The time of expensive synchronizations is taken into account. This strategy is expected to produce equal results for aggregate and non-aggregate cases.

## 4.3.1. Assured Completion of Transfers

Following the MPI standard, assured completion of transfers is the minimum sequence of operations after which all processes of the file communicator have a consistent view after a write.

The aggregate and non-aggregate modes differ in when the assured completion of data transfers takes place:

- after each transfer (non-aggregate mode)
- after a bunch of multiple transfers (aggregate mode)

For Intel® MPI Benchmarks, assured completion means the following:

- For IMB-EXT benchmarks, MPI\_Win\_fence
- For IMB-IO Write benchmarks, a triplet MPI\_File\_sync/MPI\_Barrier(file\_communicator)/MPI\_File\_sync. This fixes the non-sufficient definition in the Intel® MPI Benchmarks 3.0.

## 4.4. IMB-EXT Benchmarks

This section provides definitions of IMB-EXT benchmarks. The benchmarks can run with varying transfer sizes x, in bytes. The timings are averaged over multiple samples. See the Benchmark Methodology section for details. In the definitions below, a single sample with a fixed transfer size x is used.

The Unidir and Bidir benchmarks are exact equivalents of the message passing PingPong and PingPing, respectively. Their interpretation and output are analogous to their message passing equivalents.

## 4.4.1. Unidir\_Put

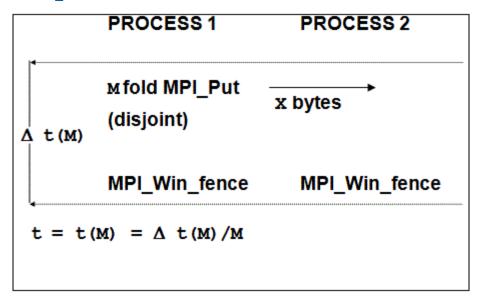

This is the benchmark for the  $\mathtt{MPI\_Put}$  function. The following table and figure provide the basic definitions and a schematic view of the pattern.

#### **Unidir Put Definition**

Property	Description
Measured pattern	As symbolized between in the figure below. This benchmark runs on two active processes ( $Q=2$ ).
MPI routine	MPI_Put
MPI data type	MPI_BYTE (origin and target)
Reported timings	t=t (M) (in $\mu$ sec) as indicated in the figure below, non-aggregate (M=1)and aggregate (M=n_sample). For details, see Actual Benchmarking.

Reported throughput	X/t, aggregate and non-aggregate
	00 0

## Unidir\_Put Pattern

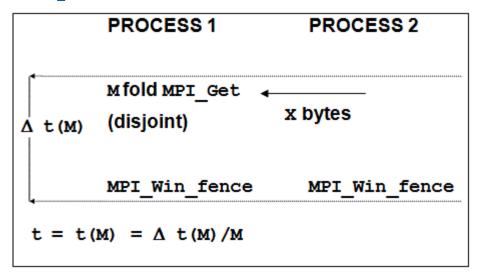

# 4.4.2. Unidir\_Get

This is the benchmark for the  ${\tt MPI\_Get}$ 

## **Unidir\_Get Definition**

Property	Description
Measured pattern	As symbolized between $\bullet$ in the figure below. This benchmark runs on two active processes (Q=2) .
MPI routine	MPI_Get
MPI data type	MPI_BYTE, for both origin and target
Reported timings	t=t (M) (in $\mu$ sec) as indicated in the figure below, non-aggregate (M=1)and aggregate (M= $n$ _sample). For details, see Actual Benchmarking.
Reported throughput	X/t, aggregate and non-aggregate

#### **Unidir\_Get Pattern**

## 4.4.3. Bidir\_Put

This is the benchmark for the MPI Put function with bidirectional transfers. See the basic definitions below.

#### **Bidir\_Put Definition**

Property	Description
Measured pattern	As symbolized between $\bullet$ in the figure below. This benchmark runs on two active processes (Q=2) .
MPI routine	MPI_Put
MPI data type	MPI_BYTE, for both origin and target
Reported timings	t=t (M) (in $\mu$ sec)as indicated in the figure below, non-aggregate (M=1)and aggregate (M= $n_sample$ ). For details, see Actual Benchmarking.
Reported throughput	X/t, aggregate and non-aggregate

## 4.4.4. Bidir\_Get

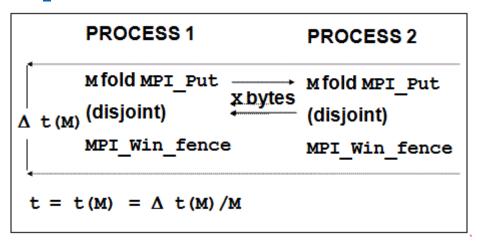

This is the benchmark for the  $\mathtt{MPI\_Get}$  function, with bidirectional transfers. Below see the basic definitions and a schematic view of the pattern.

#### **Bidir\_Get Definition**

Property	Description
Measured pattern	As symbolized between $\bullet$ in the figure below. This benchmark runs on two active processes ( $Q=2$ ).

MPI routine	MPI_Get
MPI data type	MPI_BYTE, for both origin and target
Reported timings	t=t (M) (in $\mu$ sec) as indicated in the figure below, non-aggregate (M=1)and aggregate (M= $n_sample$ ). For details, see Actual Benchmarking.
Reported throughput	X/t, aggregate and non-aggregate

#### **Bidir\_Get Pattern**

#### 4.4.5. Accumulate

This is the benchmark for the MPI\_Accumulate function. It reduces a vector of length L = x/sizeof(float) of float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. See the basic definitions and a schematic view of the pattern below.

#### **Accumulate Definition**

Property	Description
Measured pattern	As symbolized between $\bullet$ in the figure below. This benchmark runs on two active processes (Q=2) .
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Root	О
Reported timings	t=t (M) (in $\mu sec$ ) as indicated in the figure below, non-aggregate (M=1)and aggregate (M= $n_sample$ ). For details, see Actual Benchmarking.

Reported throughput	None

#### **Accumulate Pattern**

```
all active processes

Mfold MPI_Accumulate (x bytes → rank 0)
(disjoint)

Δ t(M)

MPI_Win_fence

t = t(M) = Δ t(M)/M
```

#### 4.4.6. Window

This is the benchmark for measuring the overhead of an

 ${\tt MPI\_Win\_create/MPI\_Win\_fence/MPI\_Win\_free}\ combination.\ In\ the\ case\ of\ an\ unused\ window,\ a\ negligible\ non-trivial\ action\ is\ performed\ inside\ the\ window.\ It\ minimizes\ optimization\ effects\ of\ the\ MPI\ implementation.$ 

The MPI\_Win\_fence function is called to properly initialize an access epoch. This is a correction as compared to earlier releases of the Intel® MPI Benchmarks.

See the basic definitions and a schematic view of the pattern below.

#### **Window Definition**

Property	Description
Measured pattern	MPI_Win_create/MPI_Win_fence/MPI_Win_free
Reported timings	$t=\Delta t$ (M) (in $\mu sec$ ) as indicated in the figure below.
Reported throughput	None

#### **Window Pattern**

```
MPI_Win_create (size = X)

Δ t MPI_Win_fence
MPI_Put (1 byte → Window)
MPI_Win_free
```

# 4.5. IMB-IO Blocking Benchmarks

This section describes blocking I/O benchmarks. The benchmarks can run with varying transfer sizes X, in bytes. The timings are averaged over multiple samples. The basic MPI data type for all data buffers is MPI BYTE. In the definitions below, a single sample with a fixed I/O size X is used.

Every benchmark contains an elementary I/O action, denoting a pure read or write. Thus, all benchmark flavors have a Write and a Read component. The [ACTION] placeholder denotes a Read or a Write alternatively.

The Write flavors of benchmarks include a file synchronization with different placements for aggregate and non-aggregate modes.

I/O Benchmarks, Aggregation for Output

# Output: M fold aggregation M fold elementary I/O action (output), disjoint file sections Δ t (M) MPI\_File\_sync non-aggregate mode: t = Δ t (M = 1) aggregate mode: t = Δ t (M = n\_sample) / M (choice of M = n\_sample) Input: No aggregation t = Δ t single elementary I/O action (input)

## 4.5.1. **S\_[ACTION]\_indv**

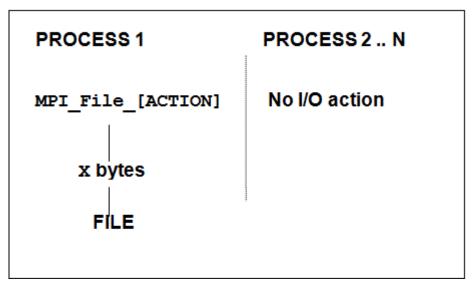

File I/O performed by a single process. This pattern mimics the typical case when a particular master process performs all of the I/O. See the basic definitions and a schematic view of the pattern below.

#### **S [ACTION] indv Definition**

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below.
MPI routines for the blocking mode	MPI_File_write/MPI_File_read
MPI routines for the nonblocking mode	MPI_File_iwrite/MPI_File_iread
etype	MPI_BYTE

File type	MPI_BYTE
MPI data type	MPI_BYTE
Reported timings	t (in $\mu sec$ ) as indicated in the figure I/O benchmarks, aggregation for output, aggregate and non-aggregate for the Write flavor.
Reported throughput	x/t, aggregate and non-aggregate for the Write flavor

#### **S\_[ACTION]\_indv Pattern**

# 4.5.2. S\_[ACTION]\_expl

This benchmark mimics the same situation as  $S_[ACTION]_{indv}$ , with a different strategy to access files. See the basic definitions and a schematic view of the pattern below.

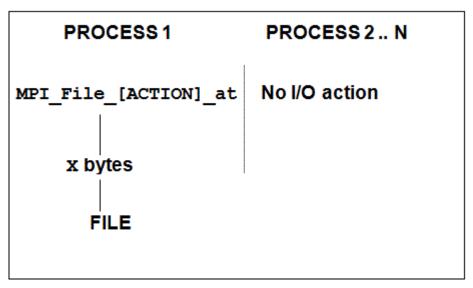

#### **S\_[ACTION]\_expl Definition**

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below.
MPI routines for the blocking mode	MPI_File_write_at/MPI_File_read_at
MPI routines for the nonblocking mode	MPI_File_iwrite_at/MPI_File_iread_at
etype	MPI_BYTE

#### Intel® MPI Benchmarks User Guide

File type	MPI_BYTE
MPI data type	MPI_BYTE
Reported timings	t (in µsec) as indicated in the figure I/O benchmarks, aggregation for output, aggregate and non-aggregate for the Write flavor.
Reported throughput	x/t, aggregate and non-aggregate for the Write flavor

#### **S\_[ACTION]\_expl** pattern

# 4.5.3. P\_[ACTION]\_indv

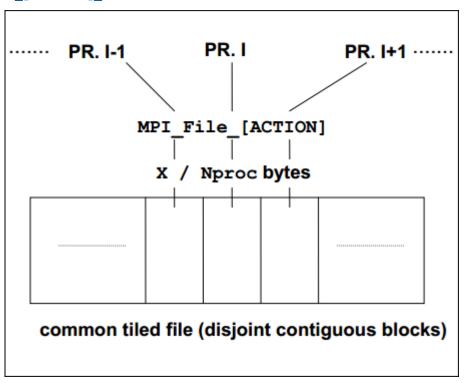

This pattern accesses the file in a concurrent manner. All participating processes access a common file. See the basic definitions and a schematic view of the pattern below.

#### P\_[ACTION]\_indv Definition

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below. In this figure, Nproc is the number of processes.
MPI routines for the blocking mode	MPI_File_write/MPI_File_read
MPI routines for the nonblocking mode	MPI_File_iwrite/MPI_File_iread
etype	MPI_BYTE
File type	Tiled view, disjoint contiguous blocks

MPI data type	MPI_BYTE
Reported timings	t (in $\mu sec$ ) as indicated in the figure I/O benchmarks, aggregation for output, aggregate and non-aggregate for the Write flavor.
Reported throughput	x/t, aggregate and non-aggregate for the Write flavor

#### P\_[ACTION]\_indv Pattern

# 4.5.4. P\_ACTION\_expl

 $\begin{tabular}{ll} $\mathbb{P}_{ACTION}_{av} & \begin{tabular}{ll} & \begin{tabular}{ll} $\mathbb{P}_{ACTION}_{av} & \begin{tabular}{ll} & \begin{tabu$ 

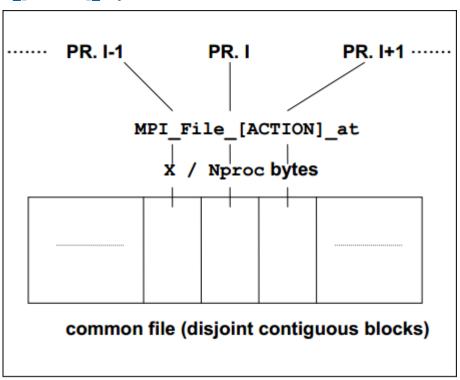

#### P\_[ACTION]\_expl Definition

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below. In this figure, Nproc is the number of processes.
MPI routines for the blocking mode	MPI_File_write_at/MPI_File_read_at
MPI routines for the nonblocking	MPI_File_iwrite_at/MPI_File_iread_at

#### Intel® MPI Benchmarks User Guide

mode	
etype	MPI_BYTE
File type	MPI_BYTE
MPI data type	MPI_BYTE
Reported timings	t (in µsec) as indicated in the figure I/O benchmarks, aggregation for output, aggregate and non-aggregate for the Write flavor.
Reported throughput	x/t, aggregate and non-aggregate for the Write flavor

#### P\_[ACTION]\_expl Pattern

# 4.5.5. P\_[ACTION]\_shared

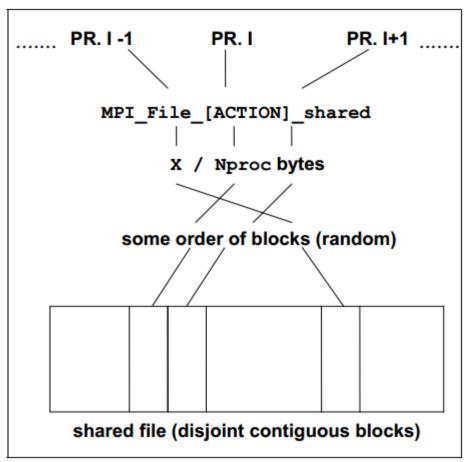

Concurrent access to a common file by all participating processes, with a shared file pointer. See the basic definitions and a schematic view of the pattern below.

## **P\_[ACTION]\_shared Definition**

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below. In this figure, Nproc is the number of processes.

MPI routines for the blocking mode	MPI_File_write_at/MPI_File_read_at
MPI routines for the nonblocking mode	MPI_File_iwrite_at/MPI_File_iread_at
etype	MPI_BYTE
File type	MPI_BYTE
MPI data type	MPI_BYTE
Reported timings	t (in µsec) as indicated in the figure I/O benchmarks, aggregation for output, aggregate and non-aggregate for the Write flavor.
Reported throughput	x/t, aggregate and non-aggregate for the Write flavor

#### P\_[ACTION]\_shared Pattern

## 4.5.6. **P\_[ACTION]\_priv**

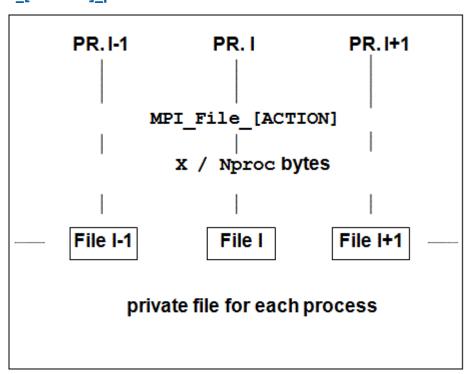

This pattern tests the case when all participating processes perform concurrent I/O to different private files. This benchmark is particularly useful for the systems that allow completely independent I/O operations from

different processes. The benchmark pattern is expected to show parallel scaling and obtain optimum results. See the basic definitions and a schematic view of the pattern below.

#### **P\_[ACTION]\_priv Definition**

Property	Description
Measured pattern	As symbolized in figure I/O benchmarks, aggregation for output
Elementary I/O action	As symbolized in the figure below. In this figure, Nproc is the number of processes.
MPI routines for the blocking mode	MPI_File_write/MPI_File_read
MPI routines for the nonblocking mode	MPI_File_iwrite/MPI_File_iread
etype	MPI_BYTE
File type	MPI_BYTE
MPI data type	MPI_BYTE
Reported timings	$\Delta t$ (in $\mu sec$ ), aggregate and non-aggregate for the $Write$ flavor.
Reported throughput	x/Δt, aggregate and non-aggregate for the Write flavor

#### P\_[ACTION]\_priv Pattern

## 4.5.7. **C\_[ACTION]\_indv**

 $C_{ACTION}$  indv tests collective access from all processes to a common file, with an individual file pointer. Below see the basic definitions and a schematic view of the pattern.

This benchmark is based on the following MPI routines:

- MPI File read all/MPI File write all for the blocking mode
- MPI File .. all begin/MPI File .. all end for the nonblocking mode

All other parameters and the measuring method are the same as for the P [ACTION] indv benchmark.

#### See Also

P [ACTION] indv

## 4.5.8. C\_[ACTION]\_expl

This pattern performs collective access from all processes to a common file, with an explicit file pointer.

This benchmark is based on the following MPI routines:

- MPI\_File\_read\_at\_all/MPI\_File\_write\_at\_all for the blocking mode
- MPI File .. at all begin/MPI File .. at all end for the nonblocking mode

All other parameters and the measuring method are the same as for the P [ACTION] expl benchmark.

#### See Also

P\_[ACTION]\_expl

## 4.5.9. C [ACTION] shared

The benchmark of a collective access from all processes to a common file, with a shared file pointer.

This benchmark is based on the following MPI routines:

- MPI File read ordered/MPI File write ordered for the blocking mode
- MPI File .. ordered begin/MPI File .. ordered end for the nonblocking mode

All other parameters and the measuring method are the same as for the  $P_[ACTION]$  shared benchmark.

#### See Also

P\_[ACTION]\_shared

## 4.5.10. Open\_Close

The benchmark for the MPI\_File\_open/MPI\_File\_close functions. All processes open the same file. To avoid MPI implementation optimizations for an unused file, a negligible non-trivial action is performed with the file. See the basic definitions of the benchmark below.

#### **Open\_Close Definition**

Property	Description
Measured pattern	MPI_File_open/MPI_File_close
etype	MPI_BYTE

File type	MPI_BYTE
Reported timings	t= $\Delta$ t (in $\mu$ sec), as indicated in the figure below.
Reported throughput	None

#### **Open\_Close Pattern**

```
all active processes

MPI_File open
Δ t MPI_File_write (1 byte → File)
MPI_File_close
```

# 4.6. IMB-IO Non-blocking Benchmarks

Intel® MPI Benchmarks implements blocking and nonblocking modes of the IMB-IO benchmarks as different benchmark flavors. The Read and Write components of the blocking benchmark name are replaced for nonblocking flavors by IRead and IWrite, respectively.

The definitions of blocking and nonblocking flavors are identical, except for their behavior in regard to:

- Aggregation. The nonblocking versions only run in the non-aggregate mode.
- Synchronism. Only the meaning of an elementary transfer differs from the equivalent blocking benchmark.

Basically, an elementary transfer looks as follows:

```
time = MPI_Wtime()
for ( i=0; i<n_sample; i++ )
{
    Initiate transfer
    Exploit CPU
    Wait for the end of transfer
}
time = (MPI_Wtime()-time)/n_sample</pre>
```

The Exploit CPU section in the above example is arbitrary. Intel® MPI Benchmarks exploits CPU as described below.

## 4.6.1. Exploiting CPU

Intel® MPI Benchmarks uses the following method to exploit the CPU. A kernel loop is executed repeatedly. The kernel is a fully vectorizable multiplication of a 100x100 matrix with a vector. The function is scalable in the following way:

```
IMB cpu exploit(float desired time, int initialize);
```

The input value of  $desired\_time$  determines the time for the function to execute the kernel loop, with a slight variance. At the very beginning, the function is called with initialize=1 and an input value for  $desired\_time$ . This determines an Mflop/s rate and a timing  $t\_CPU$ , as close as possible to  $desired\_time$ , obtained by running without any obstruction. During the actual benchmarking, IMB\_cpu\_exploit is called with initialize=0, concurrently with the particular I/O action, and always performs the same type and number of operations as in the initialization step.

# 4.6.2. Displaying Results

Three timings are crucial to interpret the behavior of nonblocking I/O, overlapped with CPU exploitation:

- t pure is the time for the corresponding pure blocking I/O action, non-overlapping with CPU activity
- t\_CPU is the time the IMB\_cpu\_exploit periods (running concurrently with nonblocking I/O) would use when running dedicated
- $t_{ovrl}$  is the time for the analogous nonblocking I/O action, concurrent with CPU activity (exploiting t CPU when running dedicated)

```
A perfect overlap means: t ovrl = max(t pure, t CPU)
```

No overlap means: t ovrl = t pure+t CPU.

The actual amount of overlap is:

```
overlap=(t pure+t CPU-t ovrl)/min(t pure, t CPU)(*)
```

The Intel® MPI Benchmarks result tables report the timings  $t_{ovrl}$ ,  $t_{pure}$ ,  $t_{CPU}$  and the estimated overlap obtained by the (\*) formula above. At the beginning of a run, the Mflop/s rate is corresponding to the to CPU displayed.

# 5. MPI-3 Benchmarks

Intel® MPI Benchmarks provides two sets of benchmarks conforming to the MPI-3 standard:

- IMB-NBC benchmarks for nonblocking collective (NBC) operations
- IMB-RMA one-sided communications benchmarks that measure the Remote Memory Access (RMA) functionality introduced in the MPI-3 standard.

## 5.1. IMB-NBC Benchmarks

Intel® MPI Benchmarks provides two types of benchmarks for nonblocking collective (NBC) routines that conform to the MPI-3 standard:

- Benchmarks for measuring the overlap of communication and computation
- Benchmarks for measuring pure communication time

#### TIP

When you run the IMB-NBC component, only the overlap benchmarks are enabled by default. To measure pure communication time, specify the particular benchmark name or use the -include command-line parameter to run the pure flavor of the benchmarks.

The following table lists all IMB-NBC benchmarks:

Benchmarks Measuring Communication and Computation Overlap (Enabled by Default)	Benchmarks Measuring Pure Communication Time (Disabled by Default)
Ibcast	Ibcast_pure
Iallgather	Iallgather_pure
Iallgatherv	Iallgatherv_pure
Igather	Igather_pure
Igatherv	Igatherv_pure
Iscatter	Iscatter_pure
Iscatterv	Iscatterv_pure
Ialltoall	Ialltoall_pure
Ialltoallv	Ialltoallv_pure
Ireduce	Ireduce_pure
Ireduce_scatter	Ireduce_scatter_pure
Iallreduce	Iallreduce_pure
Ibarrier	Ibarrier_pure

#### See Also

Measuring Communication and Computation Overlap Measuring Pure Communication Time

#### 5.1.1. Measuring Communication and Computation Overlap

Semantics of nonblocking collective operations enables you to run inter-process communication in the background while performing computations. However, the actual overlap depends on the particular MPI library implementation. You can measure a potential overlap of communication and computation using IMB-NBC benchmarks. The general benchmark flow is as follows:

- 1. Measure the time needed for a pure communication call.
- 2. Start a nonblocking collective operation.
- 3. Start computation using the IMB\_cpu\_exploit function, as described in the IMB-IO Nonblocking Benchmarks chapter. To ensure correct measurement conditions, the computation time used by the benchmark is close to the pure communication time measured at step 1.
- 4. Wait for communication to finish using the MPI Wait function.

#### **Displaying Results**

The timing values to interpret the overlap potential are as follows:

- t pure is the time of a pure communication operation, non-overlapping with CPU activity.
- t\_CPU is the time the IMB\_cpu\_exploit function takes to complete when run concurrently with the nonblocking communication operation.
- t\_ovrl is the time of the nonblocking communication operation takes to complete when run concurrently with a CPU activity.
  - If tovrl = max(t pure, t CPU), the processes are running with a perfect overlap.
  - If tovrl = t pure+t CPU, the processes are running with no overlap.

Since different processes in a collective operation may have different execution times, the timing values are taken for the process with the biggest  $t_{ovrl}$  execution time. The IMB-NBC result tables report the timings  $t_{ovrl}$ ,  $t_{pure}$ ,  $t_{ovrl}$  and the estimated overlap in percent calculated by the following formula:

```
overlap = 100.*max(0,min(1, (t pure+t CPU-t ovrl) / min(t pure, t CPU))
```

#### See Also

IMB-NBC Benchmarks
Measuring Pure Communication Time

## 5.1.2. Measuring Pure Communication Time

To measure pure execution time of nonblocking collective operations, use the \_pure flavor of the IMB-NBC benchmarks. The benchmark methodology is consistent with the one used for regular collective operations:

- Each rank performs the predefined amount of iterations and calculates the mean value.
- The basic MPI data type for all messages is MPI\_BYTE for pure data movement functions and MPI FLOAT for reductions.
- If the operation requires the root process to be specified, the root process is selected round-robin through iterations.

These benchmarks are not included into the default list of IMB-NBC benchmarks. To run a benchmark, specify the particular benchmark name or use the -include command-line parameter. For example:

```
$ mpirun -np 2 IMB-NBC Ialltoall_pure
$ mpirun -np 2 IMB-NBC -include Iallgather_pure Ialltoall_pure
```

#### **Displaying Results**

Pure nonblocking collective benchmarks show bare timing values. Since execution time may vary for different ranks, three timing values are shown: maximum, minimum, and the average time among all the ranks participating in the benchmark measurements.

#### See Also

IMB-NBC Benchmarks Measuring Communication and Computation Overlap Command-Line Control

## 5.1.3. Iallgather

The benchmark for MPI lallgather that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Iallgather/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

## 5.1.4. lallgather\_pure

The benchmark for the MPI\_Iallgather function that measures pure communication time. Every process inputs X bytes and receives the gathered X\*np bytes, where np is the number of processes.

Property	Description
Measured pattern	MPI_Iallgather/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

## 5.1.5. Iallgatherv

The benchmark for MPI lallgatherv that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Iallgatherv/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.6. Iallgatherv\_pure

The benchmark for the MPI\_Iallgatherv function that measures pure communication time. Every process inputs X bytes and receives the gathered X\*np bytes, where np is the number of processes. Unlike Iallgather pure, this benchmark shows whether MPI produces overhead.

Property	Description
Measured pattern	MPI_Iallgatherv/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

## 5.1.7. Iallreduce

The benchmark for MPI Iallreduce that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Iallreduce/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Reported timings	<ul><li>t_ovrl</li><li>t_pure</li></ul>

	<ul> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.8. lallreduce\_pure

The benchmark for the  $\texttt{MPI\_Iallreduce}$  function that measures pure communication time. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is  $\texttt{MPI\_FLOAT}$ . The MPI operation is MPI SUM.

Property	Description
Measured pattern	MPI_Iallreduce/MPI_Wait
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	None

## 5.1.9. Ialltoall

The benchmark for  ${\tt MPI\_Ialltoall}$  that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Ialltoall/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

## 5.1.10. Ialltoall\_pure

The benchmark for the MPI\_Ialltoall function that measures pure communication time. In the case of np number of processes, every process inputs X\*np bytes (X for each process) and receives X\*np bytes (X from each process).

Property	Description
Measured pattern	MPI_Ialltoall/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

#### 5.1.11. Ialltoally

The benchmark for MPI lalltoally that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Ialltoallv/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

## 5.1.12. Ialltoallv\_pure

The benchmark for the MPI\_Ialltoallv function that measures pure communication time. In the case of np number of processes, every process inputs X\*np bytes (X for each process) and receives X\*np bytes (X from each process).

Property	Description
Measured pattern	MPI_Ialltoallv/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	Bare time

Reported throughput	None
---------------------	------

#### **5.1.13. Ibarrier**

The benchmark for MPI Ibarrier that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Ibarrier/IMB_cpu_exploit/MPI_Wait
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.14. Ibarrier\_pure

The benchmark for the MPI Ibarrier function that measures pure communication time.

Property	Description
Measured pattern	MPI_Ibarrier/MPI_Wait
Reported timings	Bare time
Reported throughput	None

## 5.1.15. Ibcast

The benchmark for MPI Ibcast that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Ibcast/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>

Reported throughput
---------------------

## 5.1.16. Ibcast\_pure

The benchmark for  $\mathtt{MPI\_Ibcast}$  that measures pure communication time. The root process broadcasts  $\mathtt{X}$  bytes to all other processes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Ibcast/MPI_Wait
MPI data type	MPI_BYTE
Reported timings	Bare time
Reported throughput	None

# 5.1.17. Igather

The benchmark for MPI Igather that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Igather/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.18. Igather\_pure

The benchmark for the MPI\_Igather function that measures pure communication time. The root process inputs X\*np bytes (X from each process). All processes receive X bytes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Igather/MPI_Wait

#### Intel® MPI Benchmarks User Guide

MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

# **5.1.19.** Igatherv

The benchmark for  ${\tt MPI\_Igatherv}$  that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Igatherv/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.20. Igatherv\_pure

The benchmark for the MPI\_Igatherv function that measures pure communication time. All processes input x bytes. The root process receives x\*np bytes, where np is the number of processes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Igatherv/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

#### 5.1.21. Ireduce

The benchmark for  $\mathtt{MPI}$  Ireduce that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Ireduce/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Root	i%num_procs in iteration i
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

## 5.1.22. Ireduce\_pure

The benchmark for the MPI\_Ireduce function that measures pure communication time. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Ireduce/MPI_Wait
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

# 5.1.23. Ireduce\_scatter

The benchmark for MPI\_Ireduce\_scatter that measures communication and computation overlap. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. In the scatter phase, the L items are split as evenly as possible. To be exact, for np number of processes:

#### Intel® MPI Benchmarks User Guide

```
L = r*np+s
```

#### where

- r = |L/np|
- $s = L \mod np$

In this case, the process with rank i gets:

- r+1 items when i<s
- r items when i≥s

Property	Description
Measured pattern	MPI_Ireduce_scatter/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_FLOAT
MPI operation	MPI_SUM
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

## 5.1.24. Ireduce\_scatter\_pure

The benchmark for the MPI\_Ireduce\_scatter function that measures pure communication time. It reduces a vector of length L = X/sizeof(float) float items. The MPI data type is MPI\_FLOAT. The MPI operation is MPI\_SUM. In the scatter phase, the L items are split as evenly as possible. To be exact, for np number of processes:

$$L = r*np+s$$

#### where

- r = [L/np]
- $s = L \mod np$

In this case, the process with rank i gets:

- r+1 items when i<s
- r items when i≥s

Property	Description
Measured pattern	MPI_Ireduce_scatter/MPI_Wait
MPI data type	MPI_FLOAT

MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	None

#### **5.1.25.** Iscatter

The benchmark for  ${\tt MPI}\ {\tt Iscatter}$  that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Iscatter/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

# 5.1.26. Iscatter\_pure

The benchmark for the  $\texttt{MPI\_Iscatter}$  function that measures pure communication time. The root process inputs X\*np bytes (X for each process). All processes receive X bytes. The root of the operation is changed round-robin.

Today Today	
Property	Description
Measured pattern	MPI_Iscatter/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

#### **5.1.27. Iscattery**

The benchmark for MPI Iscattery that measures communication and computation overlap.

Property	Description
Measured pattern	MPI_Iscatterv/IMB_cpu_exploit/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	<ul> <li>t_ovrl</li> <li>t_pure</li> <li>t_CPU</li> <li>overlap=100.*max(0,min(1, (t_pure+t_CPU-t_ovrl) / min(t_pure, t_CPU))</li> <li>For details, see Measuring Communication and Computation Overlap.</li> </ul>
Reported throughput	None

#### 5.1.28. Iscatterv\_pure

The benchmark for the MPI\_Iscatterv function that measures pure communication time. The root process inputs X\*np bytes (X for each process). All processes receive X bytes. The root of the operation is changed round-robin.

Property	Description
Measured pattern	MPI_Iscatterv/MPI_Wait
MPI data type	MPI_BYTE
Root	i%num_procs in iteration i
Reported timings	Bare time
Reported throughput	None

# 5.2. IMB-RMA Benchmarks

Intel® MPI Benchmarks provides a set of remote memory access (RMA) benchmarks that use the passive target communication mode to measure one-sided operations compliant with the MPI-3 standard.

#### 5.2.1. IMB-RMA Benchmark Modes

When running the  ${\tt IMB-RMA}$  benchmarks, you can choose between the following modes:

• Standard (default) or multiple mode. You can enable the multiple mode for all IMB-RMA benchmarks using the -multi command-line parameter. For details, see Running Benchmarks in Multiple Mode.

• Aggregate or non-aggregate mode. For details on these modes, see the MPI-2 Benchmark Modes chapter. Some IMB-RMA benchmarks support the non-aggregate mode only. To determine which benchmarks can run in the aggregate mode, see Classification of IMB-RMA Benchmarks.

#### 5.2.2. Classification of IMB-RMA Benchmarks

All the IMB-RMA benchmarks fall into the following categories:

#### Single Transfer

In these benchmarks, one process accesses the memory of another process, in unidirectional or bidirectional manner. Single Transfer IMB-RMA benchmarks only run on two active processes. Throughput values are measured in MBps and can be calculated as follows:

throughput = X/time,

#### where

- time is measured in µsec.
- X is the length of a message, in bytes.

#### **Multiple Transfer**

In these benchmarks, one process accesses the memory of several other processes.

Throughput values are measured in MBps and can be calculated as follows:

throughput = X/time \* N, where

- time is measured in usec.
- X is the length of a message, in bytes.
- N is the number of target processes.

#### NOTE

The final throughput value is multiplied by the amount of target processes since the transfer is performed to every process except the origin process itself.

#### Parallel Transfer

This class contains benchmarks that operate on several processes in parallel. These benchmarks show bare timing values: maximum, minimum, and the average time among all the ranks participating in the benchmark measurements.

The table below lists all IMB-RMA benchmarks and specifies their properties:

Benchmark	Туре	Aggregated Mode
Unidir_put	Single Transfer	Supported
Unidir_get	Single Transfer	Supported
Bidir_put	Single Transfer	Supported
Bidir_get	Single Transfer	Supported
One_put_all	Multiple Transfer	N/A
One_get_all	Multiple Transfer	N/A

All_put_all	Parallel Transfer	N/A
All_get_all	Parallel Transfer	N/A
Put_local	Single Transfer	Supported
Put_all_local	Multiple Transfer	N/A
Exchange_put	Parallel Transfer	N/A
Exchange_get	Parallel Transfer	N/A
Accumulate	Single Transfer	Supported
Get_accumulate	Single Transfer	Supported
Fetch_and_op	Single Transfer	Supported
Compare_and_swap	Single Transfer	Supported
Truly_passive_put	Single Transfer*	N/A
Get_local	Single Transfer	Supported
Get_all_local	Multiple Transfer	N/A

<sup>\*</sup> The output format differs from the regular Single Transfer output. For details, see Truly\_passive\_put.

#### 5.2.3. Accumulate

This benchmark measures the MPI\_Accumulate operation in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Accumulate/MPI_Win_flush
MPI data type	MPI_FLOAT (origin and target)
MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	MBps

# 5.2.4. All\_get\_all

The benchmark tests the scenario when all processes communicate with each other using the  $\mathtt{MPI\_Get}$  operation. To avoid congestion due to simultaneous access to the memory of a process by all other processes,

different ranks choose different targets at each particular step. For example, while looping through all the possible target ranks, the next target is chosen as follows: (target rank + current\_rank) %num\_ranks.

Property	Description
Measured pattern	(N*MPI_Get)/MPI_Win_flush_all, where N is the number of target processes
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	None

## 5.2.5. All\_put\_all

The benchmark tests the scenario when all processes communicate with each other using MPI\_Put operation. To avoid congestion due to simultaneous access to the memory of a process by all other processes, different ranks choose different targets at each particular step. For example, while looping through all the possible target ranks, the next target is chosen as follows: (target rank + current rank) %num ranks.

Property	Description
Measured pattern	(N*MPI_Put)/MPI_Win_flush_all, where N is the number of target processes
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	None

## 5.2.6. Bidir\_get

This benchmark measures the bidirectional MPI\_Get operation in passive target communication mode. The benchmark runs on two active processes. These processes initiate an access epoch to each other using the MPI Lock function, get data from the target, close the access epoch, and call the MPI Barrier function.

Property	Description
Measured pattern	MPI_Get/MPI_Win_flush
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

#### 5.2.7. Bidir put

This benchmark measures the bidirectional MPI\_Put operation in passive target communication mode. The benchmark runs on two active processes. These processes initiate an access epoch to each other using the MPI Lock function, transfer data, close the access epoch, and call the MPI Barrier function.

Property	Description
Measured pattern	MPI_Put/MPI_Win_flush
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

## 5.2.8. Compare\_and\_swap

This benchmark measures the MPI\_Compare\_and\_swap operation in passive target communication mode. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Compare_and_swap/MPI_Win_flush
MPI data type	MPI_INT (origin and target)
Reported timings	Bare time
Reported throughput	MBps

# 5.2.9. Exchange\_Get

This benchmark tests the scenario when each process exchanges data with its left and right neighbor processes using the MPI Get operation.

Property	Description
Measured pattern	(2*MPI_Get)/(2*MPI_Win_flush)
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	None

## 5.2.10. Exchange\_Put

This benchmark tests the scenario when each process exchanges data with its left and right neighbor processes using the MPI Put operation.

Property	Description
Measured pattern	(2*MPI_Put)/(2*MPI_Win_flush)

MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	None

## 5.2.11. Fetch\_and\_op

This benchmark measures the  $\texttt{MPI\_Fetch\_and\_op}$  operation in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Fetch_and_op/MPI_Win_flush
MPI data type	MPI_FLOAT (origin and target)
MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	MBps

## 5.2.12. Get\_accumulate

This benchmark measures the MPI\_Get\_Accumulate operation in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI\_Barrier call.

Property	Description
Measured pattern	MPI_Get_Accumulate/MPI_Win_flush
MPI data type	MPI_FLOAT (origin and target)
MPI operation	MPI_SUM
Reported timings	Bare time
Reported throughput	MBps

## 5.2.13. Get\_all\_local

This benchmark tests the MPI\_Get operation where one active process obtains data from all other processes. All target processes are waiting in the MPI\_Barrier call, while the active process performs the transfers. The completion of the origin process is ensured by the MPI\_Win\_flush\_local\_all operation. Since local completion of the MPI\_Get operation is semantically equivalent to a regular completion, the benchmark flow is very similar to the One\_get\_all benchmark.

#### **NOTE**

This benchmark is not enabled in IMB-RMA by default. Specify the benchmark name in the command line or use the -include command-line parameter to run this benchmark.

Property	Description
Measured pattern	(N*MPI_Get)/MPI_Win_flush_local_all, where N is the number of target processes
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

## 5.2.14. Get\_local

This benchmark measures the combination of MPI\_Get and MPI\_Win\_flush\_all operations in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI\_Barrier call. Since local completion of the MPI\_Get operation at the origin side is semantically equivalent to a regular completion, performance results are expected to be very close to the Unidir\_Get benchmark results.

#### **NOTE**

This benchmark is not enabled in IMB-RMA by default. Specify the benchmark name in the command line or use the -include command-line parameter to run this benchmark.

Property	Description
Measured pattern	MPI_Get/MPI_Win_flush_local
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

## 5.2.15. One\_put\_all

This benchmark tests the  $\texttt{MPI\_Put}$  operation using one active process that transfers data to all other processes. All target processes are waiting in the  $\texttt{MPI\_Barrier}$  call while the origin process performs the transfers.

Property	Description
Measured pattern	(N*MPI_Put) /MPI_Win_flush_all, where N is the number of target processes

MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

## 5.2.16. One\_get\_all

This benchmark tests the MPI\_Get operation using one active process that gets data from all other processes. All target processes are waiting in the MPI\_Barrier call while the origin process accesses their memory.

Property	Description
Measured pattern	(N*MPI_Get)/MPI_Win_flush_all, where N is the number of target processes.
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

# 5.2.17. Put\_all\_local

This benchmark tests the MPI\_Put operation where one active process transfers data to all other processes. All target processes are waiting in the MPI\_Barrier call, while the origin process performs the transfers. The completion of the origin process is ensured by the MPI Win flush local all operation.

Property	Description
Measured pattern	(N*MPI_Put)/MPI_Win_flush_local_all, where N is the number of target processes
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

# **5.2.18. Put\_local**

This benchmark measures the combination of MPI\_Put and MPI\_Win\_flush\_all operations in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Put/MPI_Win_flush_local
MPI data type	MPI_BYTE (origin and target)

Reported timings	Bare time
Reported throughput	MBps

## 5.2.19. Truly\_passive\_put

This benchmark verifies whether the MPI implementation supports the truly one-sided communication mode. In this mode, the origin process can complete its access epoch even if the target process is outside the MPI stack.

The Truly passive put benchmark returns two timing values:

- The time needed for the origin process to complete the MPI\_Put operation while the target process is waiting in the MPI stack in the MPI Barrier call.
- The time needed for the origin process to complete the MPI\_Put operation while the target process performs computations outside the MPI stack before the MPI Barrier call.

To ensure measurement correctness, the time spent by the target process in the computation function should be comparable to the time needed for successful completion of the MPI Put operation by the origin process.

Property	Description
Measured pattern	MPI_Put/MPI_Win_flush, while the target process performs computations before the MPI_Barrier call
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	None

## 5.2.20. Unidir\_get

This benchmark measures the MPI\_Get operation in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Get/MPI_Win_flush
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

## 5.2.21. Unidir\_put

This benchmark measures the MPI\_Put operation in passive target communication mode. The benchmark runs on two active processes. The target process is waiting in the MPI Barrier call.

Property	Description
Measured pattern	MPI_Put/MPI_Win_flush
MPI data type	MPI_BYTE (origin and target)
Reported timings	Bare time
Reported throughput	MBps

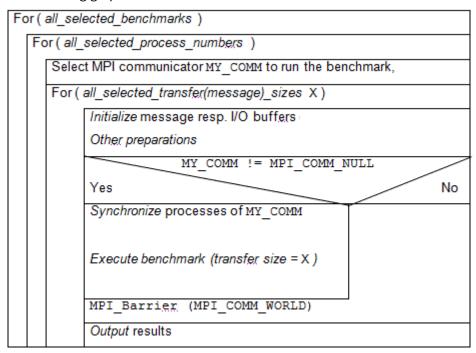

# 6. Benchmark Methodology

This section describes:

- Different ways to manage Intel® MPI Benchmarks control flow
- Command-line syntax for running the benchmarks
- Sample output data from Intel MPI Benchmarks

## 6.1. Control Flow

The following graph shows the control flow inside the Intel® MPI Benchmarks.

Intel® MPI Benchmarks provides different ways to manage its control flow:

- Hard-coded control mechanisms. For example, setting process numbers for running the central benchmarks. See the Hard-coded Settings section for details.
- Preprocessor parameters. Set the control parameters through the command line, or in the settings.h/setting\_io.h include files. See Parameters Controlling Intel® MPI Benchmarks for details.

Intel® MPI Benchmarks also offers different modes of control:

- Standard mode. In this mode, all parameters are predefined and should not be changed. This ensures comparability for result tables.
- Optional mode. In this mode, you can set these parameters at your choice. You can use this mode to extend the result tables to larger transfer sizes.

# 6.2. Command-line Control

You can control all the aspects of the Intel® MPI Benchmarks through the command-line. The general command-line syntax is the following:

```
TMB-MPT1
           [-h\{elp\}]
                       <P min>]
            [-npmin
           [-multi <outflag>]
           [-off cache <cache size[,cache line size]>
            [-iter <msgspersample[,overall vol[,msgs nonaggr[,iter policy]]]>]
            [-iter policy
                           <iter policy>]
            [-time <max_runtime per sample>]
            [-mem
                     <max. mem usage per process>]
            [-msglen <Lengths file>]
            [-map
                      <PxQ>]
            [-input
                     <filename>)
            [-include] [benchmark1 [,benchmark2 [,...]]]
            [-exclude] [benchmark1 [,benchmark2 [,...]]]
            [-msglog [<minlog>:]<maxlog>]
           [-thread level <level>]
            [-sync <mode>]
            [-root shift <mode>]
            [-imb barrier]
            [benchmark1 [,benchmark2 [,...]]]
```

The command line is repeated in the output. The options may appear in any order.

#### **Examples:**

Get out-of-cache data for PingPong:

```
mpirun -np 2 IMB-MPI1 PingPong -off cache -1
```

Run a very large configuration, with the following parameters:

- Maximum iterations: 20
- Maximum run time per message: 1.5 seconds
- Maximum message buffer size: 2 GBytes

```
mpirun -np 512 IMB-MPI1 -npmin 512 alltoallv -iter 20 -time 1.5 -mem 2
```

Run the P Read shared benchmark with the minimum number of processes set to seven:

```
mpirun -np 14 IMB-IO P Read shared -npmin 7
```

Run the IMB-MPI1 benchmarks including PingPongAnySource and PingPingAnySource, but excluding the Alltoall and Alltoallv benchmarks. Set the transfer message sizes as 0, 4, 8, 16, 32, 64, 128:

```
mpirun -np 16 IMB-MPI1 -msglog 2:7 -include PingPongAnySource PingPingAnySource -
exclude Alltoall Alltoally
```

Run the PingPong, PingPing, PingPongAnySource and PingPingAnySource benchmarks with the transfer message sizes 0, 2<sup>0</sup>, 2<sup>1</sup>, 2<sup>2</sup>, ..., 2<sup>16</sup>:

```
mpirun -np 4 IMB-MPI1 -msglog 16 PingPong PingPing PingPongAnySource PingPingAnySource
```

## **6.2.1. Benchmark Selection Arguments**

Benchmark selection arguments are a sequence of blank-separated strings. Each string is the name of a benchmark in exact spelling, case insensitive.

For example, the string IMB-MPI1 PingPong Allreduce specifies that you want to run PingPong and Allreduce benchmarks only:

```
mpirun -np 10 IMB-MPI1 PingPong Allreduce
```

By default, all benchmarks of the selected component are run.

## 6.2.2. -npmin Option

Specifies the minimum number of processes  $P_{\min}$  to run all selected benchmarks on. The  $P_{\min}$  value after -npmin must be an integer.

Given P min, the benchmarks run on the processes with the numbers selected as follows:

```
P min, 2P min, 4P min, ..., largest 2xP min <P, P
```

#### **NOTE**

You may set P min to 1. If you set P min > P, Intel MPI Benchmarks interprets this value as P min = P.

For example, to run the IMB-EXT benchmarks with minimum number of processes set to five, call: mpirun -np 11 IMB-EXT -npmin 5

By default, all active processes are selected as described in the Running Intel® MPI Benchmarks section.

## 6.2.3. -multi Option

Defines whether the benchmark runs in multiple mode. In this mode MPI\_COMM\_WORLD is split into several groups, which run simultaneously. The argument after -multi is a meta-symbol <outflag> that can take an integer value of 0 or 1:

- Outflag = 0 display only maximum timings (minimum throughputs) over all active groups
- Outflag = 1 report on all groups separately. The report may be long in this case.

When the number of processes running the benchmark is more than half of the overall number  $\texttt{MPI\_COMM\_WORLD}$ , the multiple benchmark coincides with the non-multiple one, as not more than one process group can be created.

For example, if you run this command:

```
mpirun -np 16 IMB-MPI1 -multi 0 bcast -npmin 12
```

The benchmark will run in non-multiple mode, as the benchmarking starts from 12 processes, which is more than half of MPI COMM WORLD.

By default, Intel® MPI Benchmarks run non-multiple benchmark flavors.

# 6.2.4. -off\_cache cache\_size[,cache\_line\_size] Option

Use the  $-off_cache$  flag to avoid cache re-use. If you do not use this flag (default), the same communications buffer is used for all repetitions of one message size sample. In this case, Intel® MPI Benchmarks reuses the cache, so throughput results might be non-realistic.

The argument after off\_cache can be a single number (cache\_size), two comma-separated numbers (cache size, cache line size), or -1:

- cache size is a float for an upper bound of the size of the last level cache, in MB.
- cache line size is assumed to be the size of a last level cache line (can be an upper estimate).
- -1 uses values defined in IMB\_mem\_info.h. In this case, make sure to define values for cache\_size and cache line size in IMB mem info.h.

The sent/received data is stored in buffers of size ~2x MAX (cache\_size, message\_size). When repetitively using messages of a particular size, their addresses are advanced within those buffers so that a single message is at least 2 cache lines after the end of the previous message. When these buffers are filled up, they are reused from the beginning.

-off cache is effective for IMB-MPI1 and IMB-EXT. Avoid using this option for IMB-IO.

#### **Examples:**

Use the default values defined in IMB mem info.h:

```
-off cache -1
```

2.5 MB last level cache, default line size:

```
-off cache 2.5
```

16 MB last level cache, line size 128:

```
-off cache 16,128
```

The off\_cache mode might also be influenced by eventual internal caching with the Intel® MPI Library. This could make results interpretation complicated.

Default: no cache control.

### 6.2.5. -iter Option

Use this option to control the number of iterations executed by every benchmark.

By default, the number of iterations is controlled through parameters MSGSPERSAMPLE, OVERALL\_VOL, MSGS\_NONAGGR, and ITER\_POLICY defined in IMB\_settings.h.

You can optionally add one or more arguments after the -iter flag, to override the default values defined in settings.h. Use the following guidelines for the optional arguments:

- To override the MSGSPERSAMPLE value, use a single integer.
- To override the OVERALL\_VOL value, use two comma-separated integers. The first integer defines the MSGSPERSAMPLE value. The second integer overrides the OVERALL VOL value.
- To override the MSGS\_NONAGGR value, use three comma-separated integer numbers. The first integer defines the MSGSPERSAMPLE value. The second integer overrides the OVERALL\_VOL value. The third overrides the MSGS\_NONAGGR value.
- To override the -iter\_policy argument, enter it after the integer arguments, or right after the -iter flag if you do not use any other arguments.

#### **Examples:**

To define MSGSPERSAMPLE as 2000, and OVERALL VOL as 100, use the following string:

```
-iter 2000,100
```

To define MSGS\_NONAGGR as 150, you need to define values for MSGSPERSAMPLE and OVERALL\_VOL as shown in the following string:

```
-iter 1000,40,150
```

To define MSGSPERSAMPLE as 2000 and set the multiple\_np policy, use the following string (see – iter policy):

```
-iter 2000, multiple np
```

## 6.2.6. -iter\_policy Option

Use this option to set a policy for automatic calculation of the number of iterations. Use one of the following arguments to override the default ITER POLICY value defined in IMB settings.h:

Policy	Description
dynamic	Reduces the number of iterations when the maximum run time per sample (see -time) is expected to be reached. Using this policy ensures faster execution, but may lead to inaccuracy of the results.

multiple_np	Reduces the number of iterations when the message size is getting bigger. Using this policy ensures the accuracy of the results, but may lead to longer execution time. You can control the execution time through the -time option.
auto	<ul> <li>Automatically chooses which policy to use:</li> <li>applies multiple_np to collective operations where one of the processes acts as the root of the operation (for example, MPI_Bcast)</li> <li>applies dynamic to all other types of operations</li> </ul>
off	The number of iterations does not change during the execution.

You can also set the policy through the -iter option. See -iter.

By default, the ITER POLICY defined in IMB\_settings.h is used.

## 6.2.7. -time Option

Specifies the number of seconds for the benchmark to run per message size. The argument after -time is a floating-point number.

The combination of this flag with the -iter flag or its default alternative ensures that the Intel® MPI Benchmarks always chooses the maximum number of repetitions that conform to all restrictions.

A rough number of repetitions per sample to fulfill the -time request is estimated in preparatory runs that use ~1 second overhead.

Default: -time is activated. The floating-point value specifying the run-time seconds per sample is set in the SECS PER SAMPLE variable defined in IMB settings.h, or IMB settings io.h.

## 6.2.8. -mem Option

Specifies the number of GB to be allocated per process for the message buffers. If the size is exceeded, a warning is returned, stating how much memory is required for the overall run.

The argument after -mem is a floating-point number.

Default: the memory is restricted by MAX MEM USAGE defined in IMB mem info.h.

## 6.2.9. -input <File> Option

Use the ASCII input file to select the benchmarks. For example, the IMB SELECT EXT file looks as follows:

```
#
# IMB benchmark selection file
#
# Every line must be a comment (beginning with #), or it
# must contain exactly one IMB benchmark name
#
#Window
Unidir_Get
#Unidir_Put
#Bidir_Put
Accumulate
```

With the help of this file, the following command runs only <code>Unidir\_Get</code> and <code>Accumulate</code> benchmarks of the <code>IMB-EXT</code> component:

```
mpirun .... IMB-EXT -input IMB_SELECT_EXT
```

## 6.2.10. -msglen <File> Option

Enter any set of non-negative message lengths to an ASCII file, line by line, and call the Intel® MPI Benchmarks with arguments:

-msglen Lengths

The Lengths value overrides the default message lengths. For IMB-IO, the file defines the I/O portion lengths.

### 6.2.11. -map PxQ Option

Use this option to number the processes along rows of the matrix:

0	P	 (Q-2)P	(Q-1)P
1			
P-1	2P-1	(Q-1)P-1	QP-1

For example, to run Multi-PingPongbetween two nodes of size P, with each process on one node communicating with its counterpart on the other, call:

mpirun -np <2P> IMB-MPI1 -map <P>x2 PingPong

## 6.2.12. -include [[benchmark1] benchmark2 ...]

Specifies the list of additional benchmarks to run. For example, to add PingPongAnySource and PingPingAnySource benchmarks, call:

mpirun -np 2 IMB-MPI1 -include PingPongAnySource PingPingAnySource

## 6.2.13. -exclude [[benchmark1] benchmark2 ...]

Specifies the list of benchmarks to be excluded from the run. For example, to exclude Alltoall and Allgather, call:

mpirun -np 2 IMB-MPI1 -exclude Alltoall Allgather

## 6.2.14. -msglog [<minlog>:]<maxlog>

This option allows you to control the lengths of the transfer messages. This setting overrides the MINMSGLOG and MAXMSGLOG values. The new message sizes are 0, 2^minlog, ..., 2^maxlog.

For example, if you run the following command line:

mpirun -np 2 IMB-MPI1 -msglog 3:7 PingPong

Intel® MPI Benchmarks selects the lengths 0, 8, 16, 32, 64, 128, as shown below:

```
# Benchmarking PingPong
# #processes = 2
                          t[µsec] Mbytes/sec
      #bytes #repetitions
         0
                           0.70
                                   0.00
             1000
          8
                  1000
                              0.73
                                        10.46
         16
                  1000
                              0.74
                                        20.65
         32
                                        32.61
                  1000
                              0.94
                   1000
                              0.94
                                        65.14
```

128 1000 1.06 115.16

Alternatively, you can specify only the maxlog value, enter:

mpirun -np 2 IMB-MPI1 -msglog 3 PingPong

In this case Intel® MPI Benchmarks selects the lengths 0, 1, 2, 4, 8:

```
# Benchmarking PingPong
# #processes = 2
                            t[µsec] Mbytes/sec
      #bytes #repetitions
           0
                   1000
                              0.69
                                            0.00
                                0.72
           1
                    1000
                                             1.33
                    1000
                                0.71
                                             2.69
           4
                    1000
                                0.72
                                            5.28
                    1000
                                0.73
                                            10.47
```

## 6.2.15. -thread\_level Option

This option specifies the desired thread level for MPI\_Init\_thread(). See description of MPI\_Init\_thread() for details. The option is available only if the Intel® MPI Benchmarks is built with the USE\_MPI\_INIT\_THREAD macro defined. Possible values for <level> are single, funneled, serialized, and multiple.

## 6.2.16. -sync Option

This option is relevant only for benchmarks measuring collective operations. It controls whether all ranks are synchronized after every iteration step by means of the MPI\_Barrier operation. The -sync option can take the following arguments:

Argument	Description
0   off   disable   no	Disables processes synchronization at each iteration step.
1   on   enable   yes	Enables processes synchronization at each iteration step. This is the default value.

## 6.2.17. -root\_shift Option

This options is relevant only for benchmarks measuring collective operations that utilize the root concept (for example MPI\_Bcast, MPI\_Reduce, MPI\_Gather, etc). It defines whether the root is changed at every iteration step or not. The -root shift option can take the following arguments:

Argument	Description
0   off   disable   no	Disables root change at each iteration step. Rank 0 acts as a root at each iteration step. This is the default value.
1   on   enable   yes	Enables root change at each iteration step. Root rank is changed in a round-robin fashion.

## 6.2.18. -imb\_barrier Option

Implementation of the MPI\_Barrier operation may vary depending on the MPI implementation. Each MPI implementation might use a different algorithm for the barrier, with possibly different synchronization characteristics, so the Intel MPI Benchmarks results may vary significantly as a result of MPI\_Barrier implementation differences. The internal, MPI-independent barrier function IMB\_barrier is provided to make the synchronization effect more reproducible.

Use this option to use the  ${\tt IMB\_barrier}$  function to get consistent results of collective operation benchmarks.

Argument	Description
0   off   disable   no	Use the standard MPI_Barrier operation. This is the default value.
1   on   enable   yes	Use the internal barrier implementation for synchronization.

# 6.3. Parameters Controlling Intel® MPI Benchmarks

Parameters controlling the default settings of the Intel® MPI Benchmarks are set by preprocessor definition in files IMB\_settings.h (for IMB-MPI1 and IMB-EXT benchmarks) and IMB\_settings\_io.h (for IMB-IO benchmarks). Both include files have identical structure, but differ in the predefined parameter values.

To enable the optional mode, define the IMB\_OPTIONAL parameter in the IMB\_settings.h/IMB\_settings\_io.h. After you change the settings in the optional section, you need to recompile the Intel® MPI Benchmarks.

The following table describes the Intel MPI Benchmarks parameters and lists their values for the standard mode.

Parameter	Values in IMB_settings.h	Values in IMB_settings_io.h	Description
USE_MPI_INIT_THREAD	Not set	Not set	Set to initialize Intel® MPI Benchmarks by MPI_Init_thread() instead of MPI_Init()
IMB_OPTIONAL	Not set	Not set	Set to activate optional settings
MINMSGLOG	0	0	The second smallest data transfer size is max (unit, 2 <sup>MINMSGLOG</sup> (the smallest size is always 0), where unit=sizeof(float) for reductions, unit=1 for all other cases.  You can override this parameter value using the -msglog flag.
MAXMSGLOG	22	24	The largest message size used is 2 <sup>MAXMSGLOG</sup> You can override this parameter value using the - msglog flag.
ITER_POLICY	imode_dynamic		The policy used for calculating the number of iterations.

			You can override this parameter value using the - iter_policy or -iter flag.
MSGSPERSAMPLE	1000	50	The maximum repetition count for all IMB-MPI1 benchmarks. You can override this parameter value using the -iter flag.
MSGS_NONAGGR	100	10	The maximum repetition count for non-aggregate benchmarks (relevant only for IMB-EXT). You can override this parameter value using the $-time$ flag.
OVERALL_VOL	40 Mbytes	16*1048576	For all sizes smaller than OVERALL_VOL, the repetition count is reduced so that not more than OVERALL_VOL bytes are processed all in all. This permits you to avoid unnecessary repetitions for large message sizes. Finally, the real repetition count for message size X is MSGSPERSAMPLE (X=0), max(1,min(MSGSPERSAMPLE,OVERALL_VOL/X))(X>0)  Note that OVERALL_VOL does not restrict the size of the maximum data transfer. 2MAXMSGLOG OVERALL_VOL.  You can override this parameter value using the -
			mem flag.
SECS_PER_SAMPLE	10		Number of iterations is dynamically set so that this number of run time seconds is not exceeded per message length.
N_BARR	2	2	Number of MPI_Barrier for synchronization.
TARGET_CPU_SECS	0.01 seconds	0.1 seconds	CPU seconds (as float) to run concurrently with nonblocking benchmarks (irrelevant for IMB-MPI1)

In the example below, the <code>IMB\_settings\_io.h</code>. file has the <code>IMB\_OPTIONAL</code> parameter enabled, so that user-defined parameters are used. I/O sizes of 32 and 64 MB, and a smaller repetition count are selected, extending the standard mode tables. You can modify the optional values as required.

```
#define FILENAME IMB_out
#define IMB_OPTIONAL
#ifdef IMB_OPTIONAL
#define MINMSGLOG 25
#define MAXMSGLOG 26
#define MSGSPERSAMPLE 10
#define MSGS_NONAGGR 10
#define OVERALL_VOL 16*1048576
#define SECS_PER_SAMPLE 10
#define TARGET_CPU_SECS 0.1 /* unit seconds */
#define N_BARR 2
#else
/*Do not change anything below this line*/
#define MINMSGLOG 0
```

```
#define MAXMSGLOG 24
#define MSGSPERSAMPLE 50
#define MSGS_NONAGGR 10
#define OVERALL_VOL 16*1048576
#define TARGET_CPU_SECS 0.1 /* unit seconds */
#define N_BARR 2
#endif
```

If IMB OPTIONAL is deactivated, Intel MPI Benchmarks uses the default standard mode values.

# **6.4.** Hard-Coded Settings

The sections below describe Intel® MPI Benchmarks hard-coded settings. These are the settings that you can change through the command line, or in the source code directly:

- Communicators, Active Processes
- Message /I-O Buffer Lengths
- Buffer Initialization
- Other Preparations for Benchmarking
- Warm-Up Phase (MPI-1, EXT)
- Synchronization
- Actual Benchmarking

### 6.4.1. Communicators, Active Processes

Communicator management is repeated in every "select MY\_COMM" step. If it exists, the previous communicator is freed. When you run  $Q \le P$  processes, the first Q ranks of MPI\_COMM\_WORLD are put into one group, and the remaining P - Q get MPI COMM\_NULL.

The group of MY COMM calls the active processes group.

## 6.4.2. Message/I-O Buffer Lengths

#### IMB-MPI1, IMB-EXT

Set in IMB settings.h and used unless the -msglen flag is selected.

#### **IMB-IO**

Set in IMB settings io.h and used unless the -msglen flag is selected.

#### 6.4.3. Buffer Initialization

Communication and I/O buffers are dynamically allocated as <code>void\*</code> and used as <code>MPI\_BYTE</code> buffers for all benchmarks except <code>Accumulate</code>, see Memory Requirements. To assign the buffer contents, a cast to an assignment type is performed. This facilitates result checking which may become necessary. Besides, a sensible data type is mandatory for <code>Accumulate</code>.

Intel® MPI Benchmarks sets the buffer assignment type <code>assign\_type</code> in <code>IMB\_settings.h/IMB\_settings\_io.h</code>. Currently, <code>int</code> is used for <code>IMB-IO</code>, float for <code>IMB-EXT</code>. The values are set by a macro definition as follows.

#### For IMB-EXT benchmarks:

```
#define BUF_VALUE(rank,i) (0.1*((rank)+1)+(float)( i)
```

#### For IMB-IO benchmarks:

```
#define BUF VALUE(rank,i) 10000000*(1+rank)+i%10000000
```

In every initialization, communication buffers are seen as typed arrays and initialized as follows:

```
((assign_type*)buffer)[i] = BUF_VALUE(rank,i;
```

where rank is the MPI rank of the calling process.

## 6.4.4. Other Preparations for Benchmarking

#### Window (IMB-EXT and IMB-RMA)

- 1. An Info is set and MPI Win create is called, creating a window of size X for MY COMM.
- 2. For IMB-EXT, MPI Win fence is called to start an access epoch.

#### NOTE

 ${\tt IMB-RMA}\ benchmarks\ do\ not\ require\ {\tt MPI\_Win\_fence}\ since\ they\ use\ passive\ target\ communication\ mode.$ 

#### File (IMB-IO)

To initialize the IMB-IO file, follow these steps:

- 1. Select a file name. This parameter is located in the <code>IMB\_settings\_io.h</code> include file. In the case of a <code>multi-<MPI command></code>, a suffix <code>\_g<groupid></code> is appended to the name. If the file name is per process, a second event suffix <code>\_sappended</code>.
- 2. Delete the file if it exists: open the file with MPI\_MODE\_DELETE\_ON\_CLOSE and close it. The file is deleted.
- 3. Select a communicator to open the file: MPI COMM SELF for S benchmarks and P [ACTION] priv.
- 4. Select a mode: MPI MODE CREATE | MPI MODE RDWR
- 5. Select an info routine as explained below.

#### Info

Intel® MPI Benchmarks uses an external function <code>User\_Set\_Info</code> which you implement for your local system. The default version is:

```
#include mpi.h
void User_Set_Info ( MPI_Info* opt_info)
#ifdef MPIIO
{/* Set info for all MPI_File_open calls */
*opt_info = MPI_INFO_NULL;
}
#endif
#ifdef EXT
{/* Set info for all MPI_Win_create calls */
*opt_info = MPI_INFO_NULL;
}
#endif
```

The Intel® MPI Benchmarks has no assumptions or restrictions on the implementation of this routine.

#### View (IMB-IO)

The file view is determined by the following settings:

- disp = 0,
- datarep = native
- etype, filetypeas defined in the IMB-IO Blocking Benchmarks section
- info as defined in the "Info" section above

# 6.4.5. Warm-Up Phase (IMB-MPI1, IMB-EXT, IMB-NBC, and IMB-RMA)

Before starting the actual benchmark measurement for <code>IMB-MPI1</code>, <code>IMB-EXT</code>, <code>IMB-NBC</code>, and <code>IMB-RMA</code>, the selected benchmark is executed <code>N\_WARMUP</code> times with a <code>sizeof(assign\_type)</code> message length. The <code>N\_WARMUP</code> value is defined in <code>IMB\_settings.h</code>, see Parameters Controlling Intel® MPI Benchmarks for details. The warm-up phase eliminates the initialization overhead from the benchmark measurement.

## 6.4.6. Synchronization

Before the actual benchmark measurement is performed, several consecutive barrier calls are made to ensure perfect processes synchronization. The  $N_BARR$  constant defines the number of consecutive calls. The constant is defined in IMB settings. h and IMB settings io.h, with the current value of 2.

The barrier calls are either ordinary MPI\_Barrier (comm) calls, or IMB\_barrier (comm) calls (in the case the -imb\_barrier option is specified).

See figure Control flow of IMB to understand the way all the processes are synchronized.

## 6.4.7. Actual Benchmarking

To reduce measurement errors caused by insufficient clock resolution, every benchmark is run repeatedly. The repetition count is as follows:

For IMB-MPI1, IMB-NBC, and aggregate flavors of IMB-EXT, IMB-IO, and IMB-RMA benchmarks, the repetition count is MSGSPERSAMPLE. This constant is defined in IMB\_settings.h and IMB\_settings\_io.h, with 1000 and 50 values, respectively.

To avoid excessive run times for large transfer sizes X, an upper bound is set to  $OVERALL\_VOL/X$ . The  $OVERALL\_VOL$  value is defined in  $IMB\_settings.h$  and  $IMB\_settings\_io.h$ , with 4MB and 16MB values, respectively.

Given transfer size X, the repetition count for all aggregate benchmarks is defined as follows:

```
n_sample = MSGSPERSAMPLE (X=0)
n sample = max(1,min(MSGSPERSAMPLE,OVERALL VOL/X)) (X>0)
```

The repetition count for non-aggregate benchmarks is defined completely analogously, with MSGSPERSAMPLE replaced by MSGS\_NONAGGR. It is recommended to reduce the repetition count as non-aggregate run times are usually much longer.

In the following examples, elementary transfer means a pure function (MPI\_[Send, ...], MPI\_Put, MPI\_Get, MPI\_Accumulate, MPI\_File\_write\_XX, MPI\_File\_read\_XX), without any further function call. Assured completion transfer completion is:

- IMB-EXT benchmarks: MPI Win fence
- IMB-IO Write benchmarks: a triplet MPI\_File\_sync/MPI\_Barrier(file\_communicator)/MPI\_File\_sync
- IMB-RMA benchmarks: MPI\_Win\_flush, MPI\_Win\_flush\_all, MPI\_Win\_flush\_local, or MPI Win flush local all
- Other benchmarks: empty

#### **MPI-1 Benchmarks**

```
for ( i=0; i<N_BARR; i++ ) MPI_Barrier(MY_COMM)
time = MPI_Wtime()
for ( i=0; i<n sample; i++ )
   execute MPI pattern
time = (MPI_Wtime()-time)/n_sample</pre>
```

#### IMB-EXT and Blocking I/O Benchmarks

For aggregate benchmarks, the kernel loop looks as follows:

```
for ( i=0; i<N BARR; i++ )MPI Barrier(MY COMM)
/* Negligible integer (offset) calculations ... */
time = MPI_Wtime()
for ( i=0; i<n_sample; i++ )
   execute elementary transfer
   assure completion of all transfers
time = (MPI_Wtime()-time)/n_sample</pre>
```

For non-aggregate benchmarks, every transfer is completed before going on to the next transfer:

#### Non-blocking I/O Benchmarks

A nonblocking benchmark has to provide three timings:

- t pure blocking pure I/O time
- t ovrl- nonblocking I/O time concurrent with CPU activity
- t CPU pure CPU activity time

The actual benchmark consists of the following stages:

- Calling the equivalent blocking benchmark, as defined in Actual Benchmarking and taking benchmark time as t\_pure.
- Closing and re-opening the related file(s).
- Re-synchronizing the processes.
- Running the nonblocking case, concurrent with CPU activity (exploiting t\_CPU when running undisturbed), taking the effective time as t\_ovrl.

```
You can set the desired CPU time t CPU in IMB settings io.h:
```

```
#define TARGET CPU SECS 0.1 /* unit seconds */
```

# 6.5. Checking Results

To check whether your MPI implementation is working correctly, you can use the CPP flag -DCHECK.

Activate the CPP flag -DCHECK through the CPPFLAGS variable and recompile the Intel® MPI Benchmarks executable files. Every message passing result from the Intel® MPI Benchmarks are checked against the

expected outcome. Output tables contain an additional column called Defects that displays the difference as floating-point numbers.

#### NOTE

The -DCHECK results are not valid as real benchmark data. Deactivate -DCHECK and recompile to get the proper results.

# 6.6. Output

The benchmark output includes the following information:

- General information:
   machine, system, release, and version are obtained by IMB g info.c.
- The calling sequence (command-line flags) are repeated in the output chart
- Results for the non-multiple mode

After a benchmark completes, three time values are available, extended over the group of active processes:

- Tmax the maximum time
- Tmin the minimum time
- Tavg the average time

The time unit is  $\mu$ .

#### Single Transfer Benchmarks:

```
Display X = message size [bytes], T=Tmax[\musec], bandwidth = X / T Parallel Transfer Benchmarks: Display X = message; size, Tmax, Tmin and Tavg, bandwidth based on time = Tmax
```

#### **NOTE**

IMB-RMA benchmarks show only bare timings for Parallel Transfer benchmarks.

#### Collective Benchmarks:

```
Display X = message size; (except for Barrier), Tmax, Tmin; and Tavg
```

Results for the multiple mode

- -multi 0: the same as above, with min, avg over all groups.
- -multi 1: the same for all groups, max, min, avg over single groups.

## 6.6.1. Sample 1 - IMB-MPI1 PingPong Allreduce

The following example shows the results of the PingPong and Allreduce benchmark:

#### Intel® MPI Benchmarks User Guide

```
# MPI Thread Environment: MPI THREAD SINGLE
# New default behavior from Version 3.2 on:
# the number of iterations per message size is cut down
# dynamically when a certain run time (per message size sample)
# is expected to be exceeded. Time limit is defined by variable
# SECS PER SAMPLE (=> IMB settings.h)
# or through the flag => -time
# Calling sequence was:
# ./IMB-MPI1 PingPong Allreduce
# Minimum message length in bytes: 0

## 6.6.3. Sample 3 - IMB-IO p\_write\_indv

The following example shows the results of the p write indv benchmark:

```
<...> IMB-IO -np 2 p write indv -npmin 2
                      : Thu Sep 4 13:43:34 2008
# Machine
                      : x86 64
                       : Linux
# System
                      : 2.6.9-42.ELsmp

## 6.6.4. Sample 4 - IMB-EXT.exe

The example below shows the results for the Window benchmark received after running IMB-EXT.exe on a Microsoft Windows\* cluster using two processes. The performance diagnostics for Unidir\_Get, Unidir Put, Bidir Get, Bidir Put, and Accumulate are omitted.

```
<..> -n 2 IMB-EXT.exe
